- Very few questions for Week 2 :(
- We will publish few quizzes for Week 2 today

- First group assignment next week!
 - Deadline next Tuesday

How do humans see?

Hubel and Wiesel, 1959

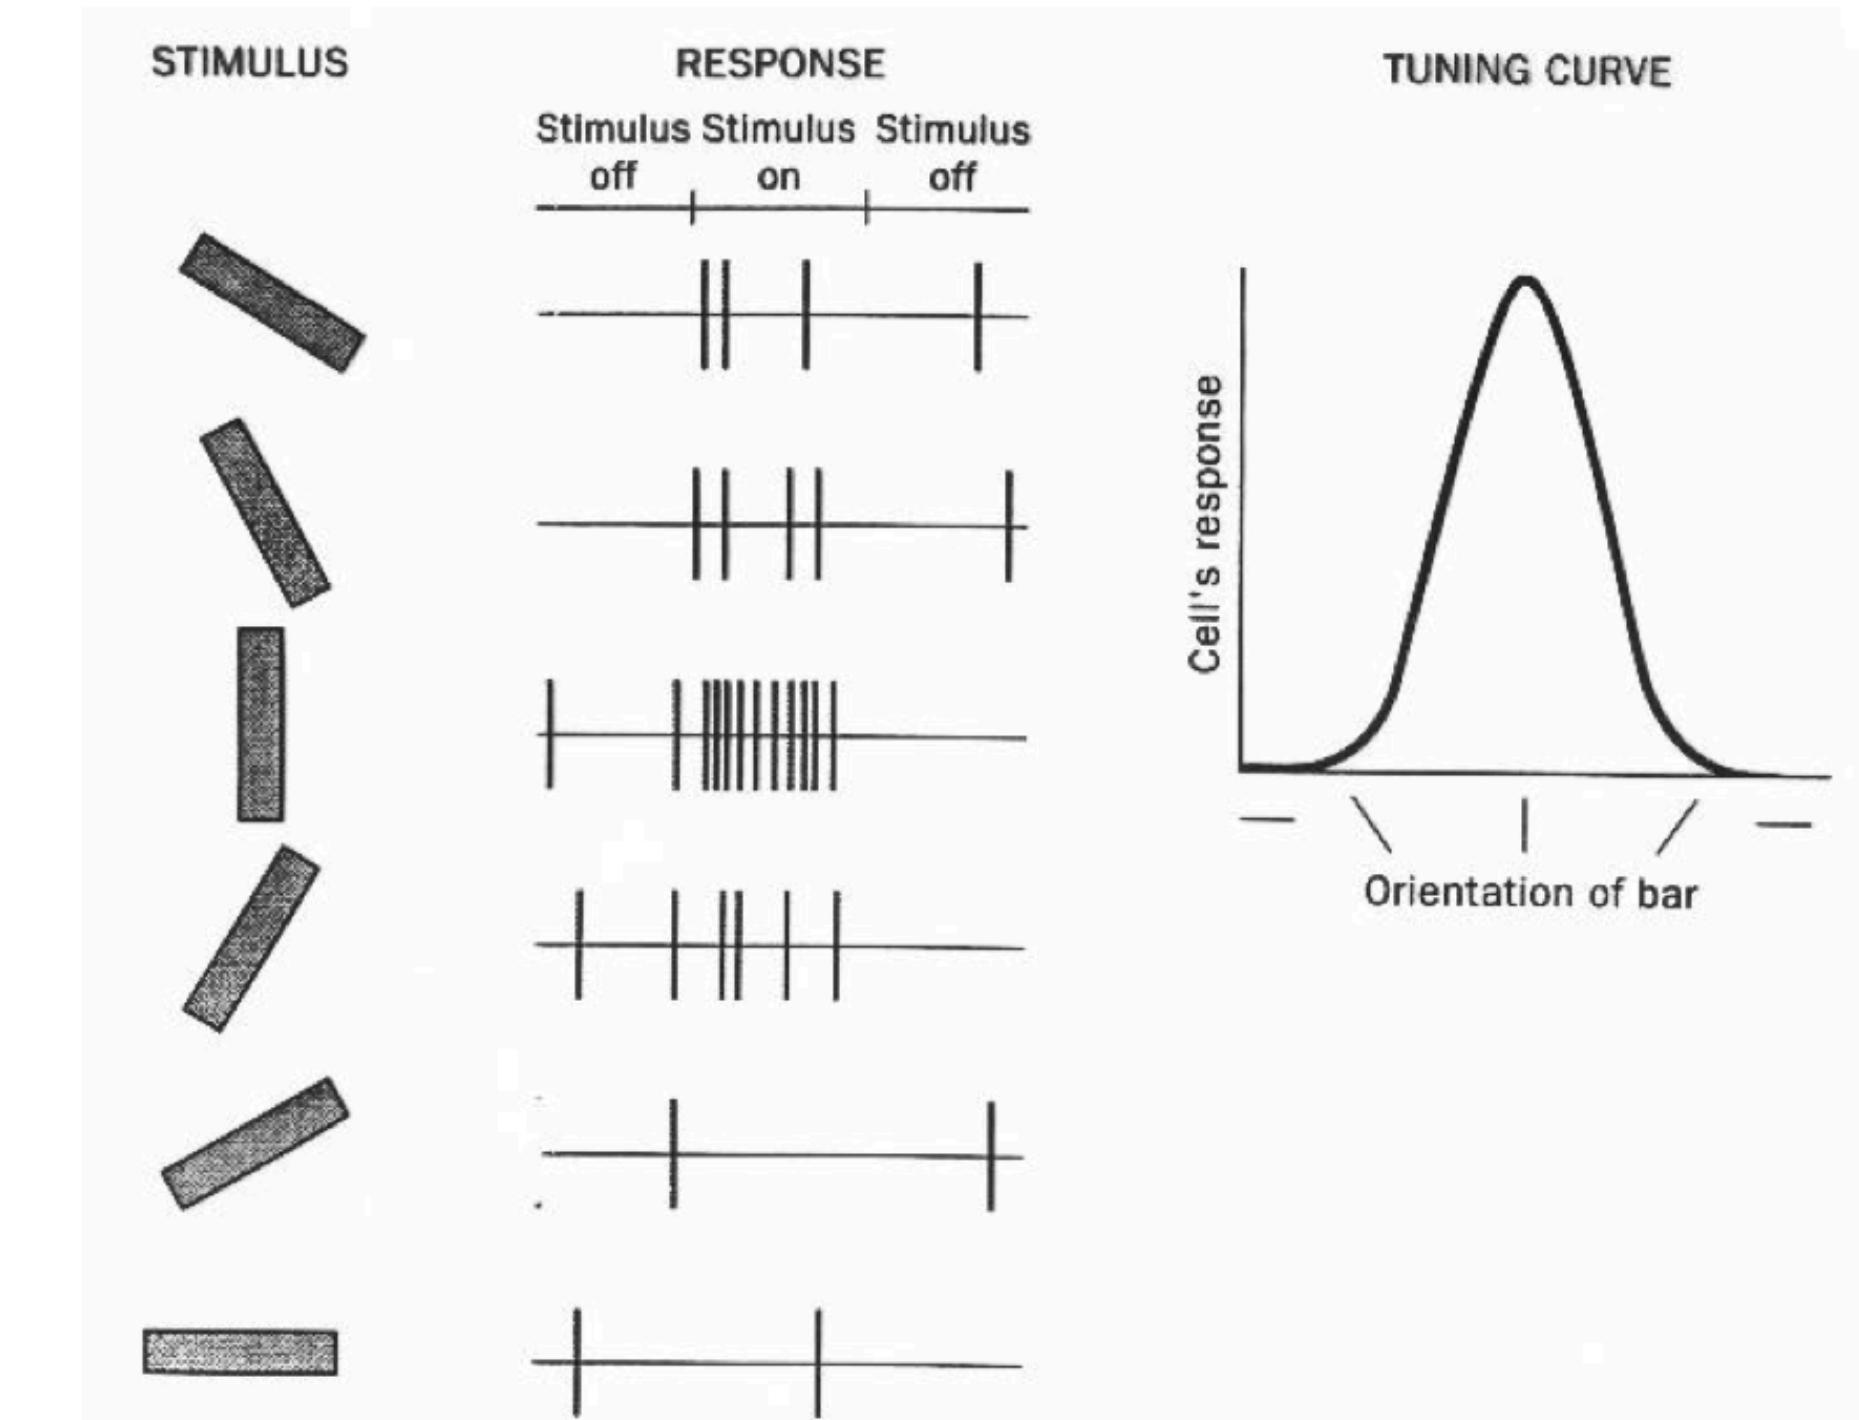

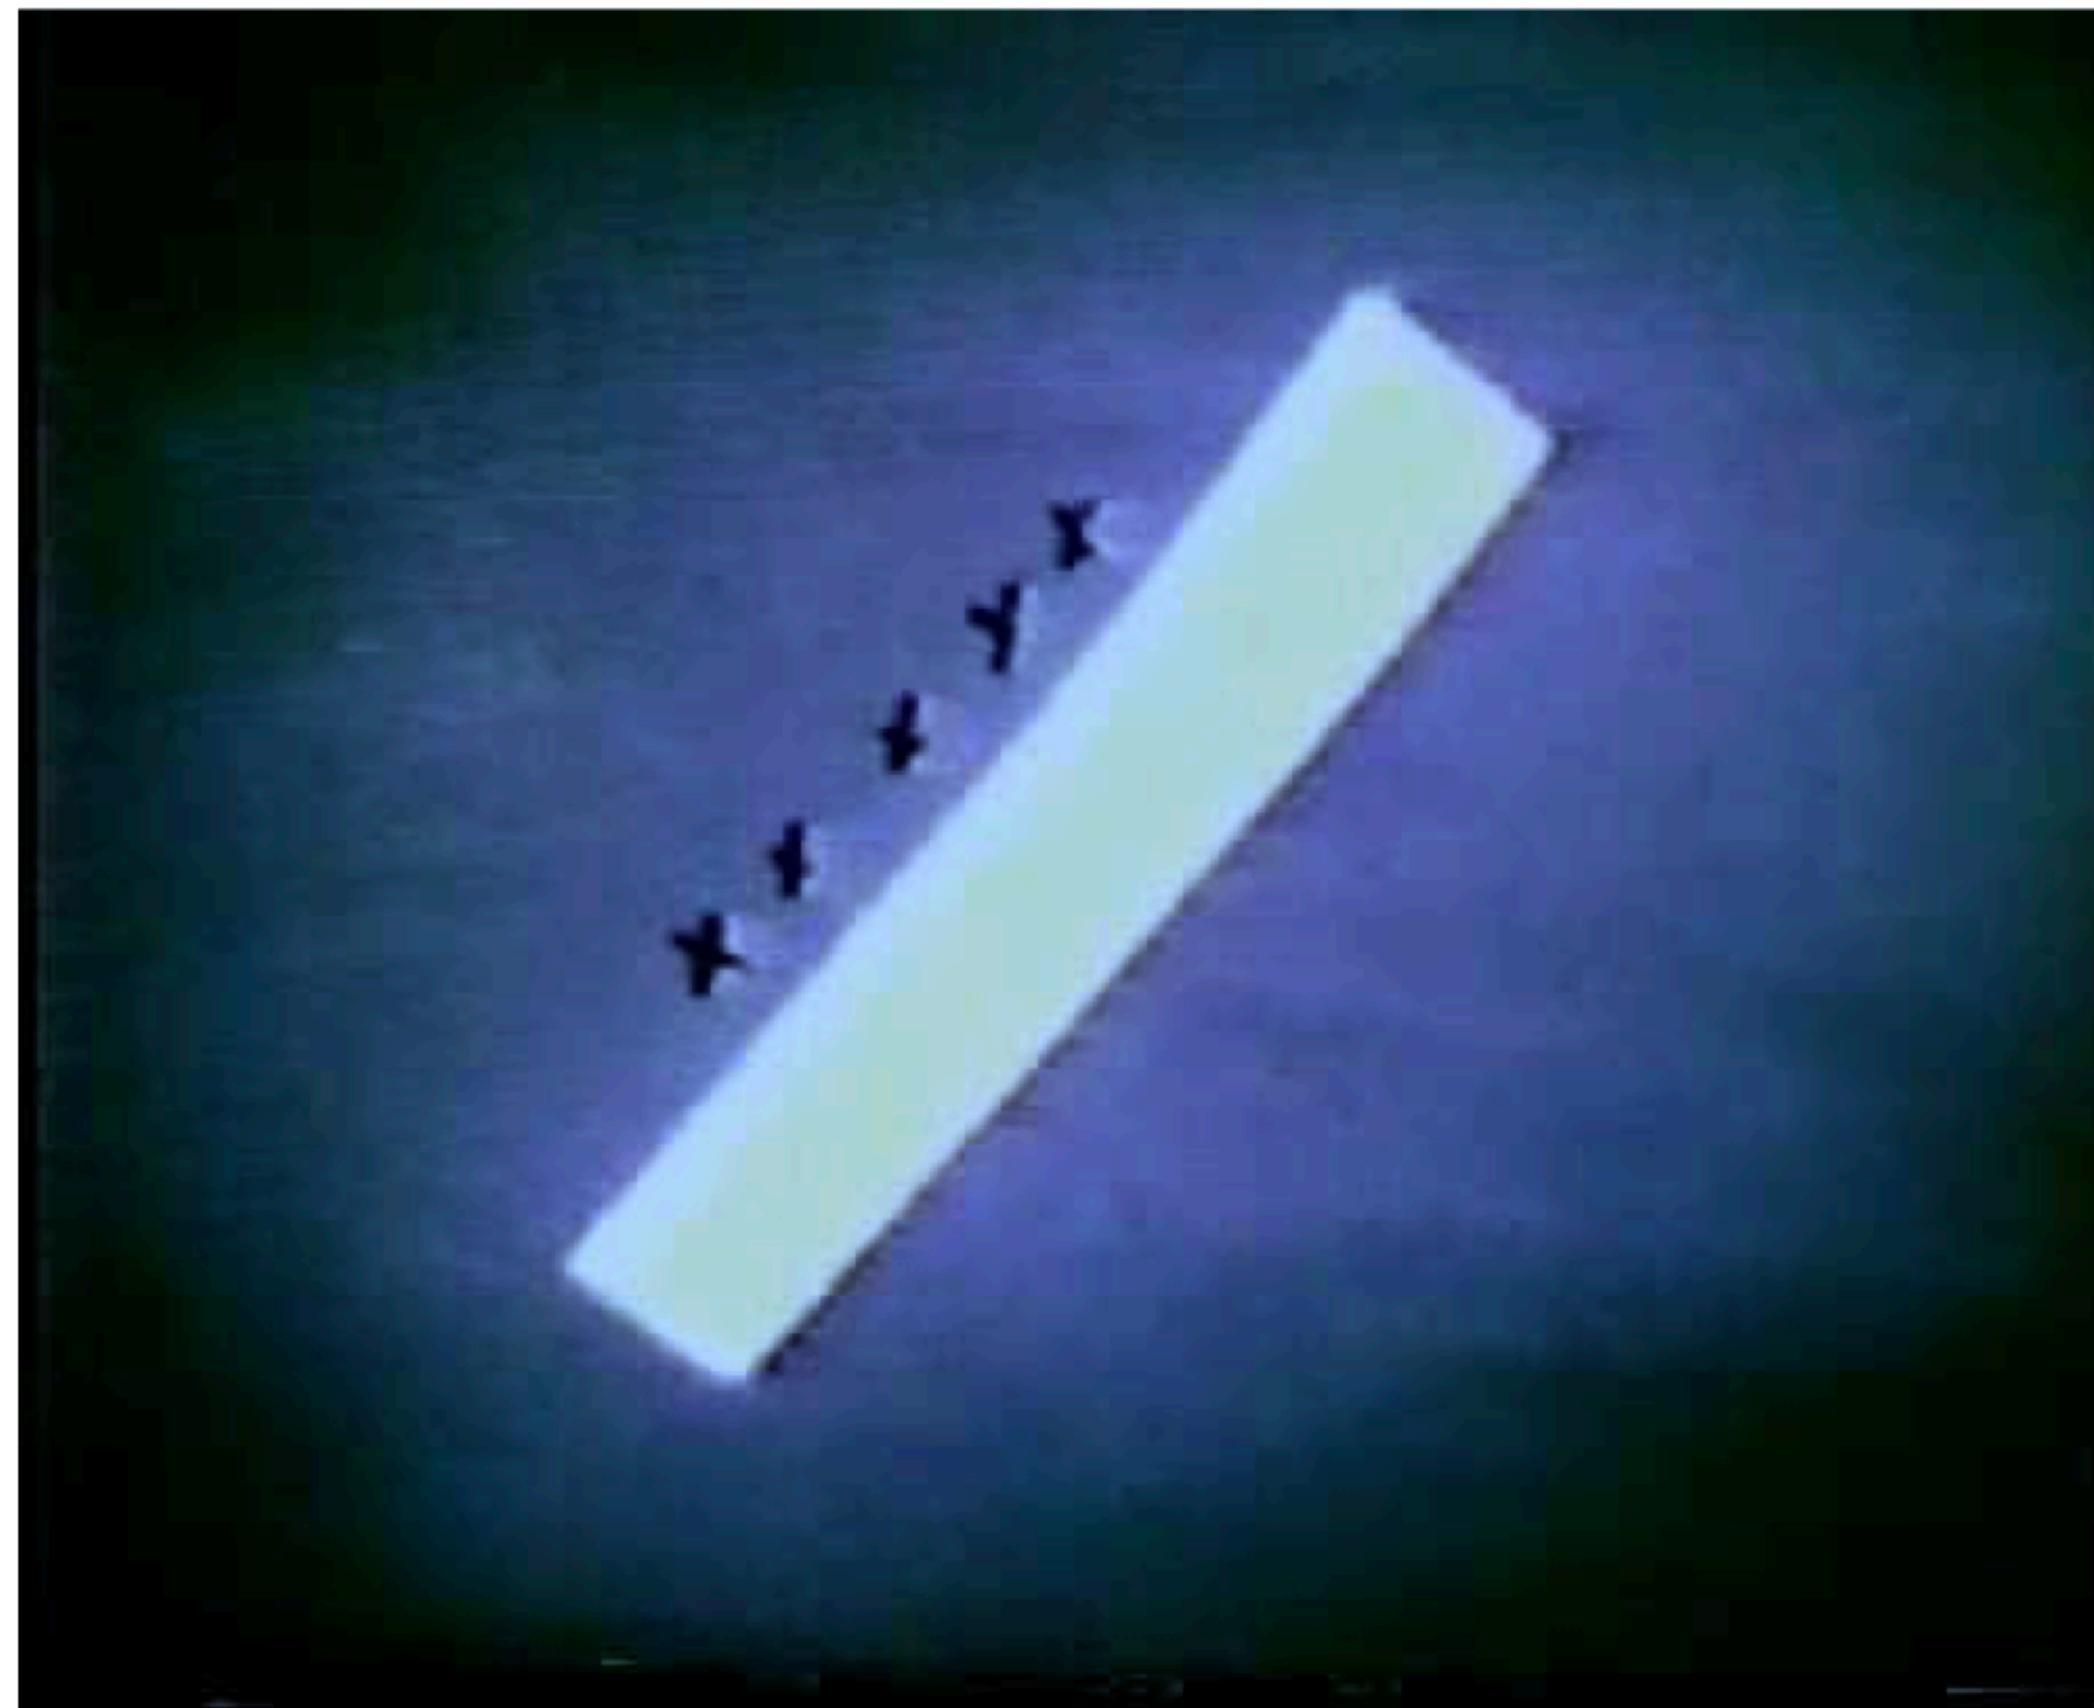

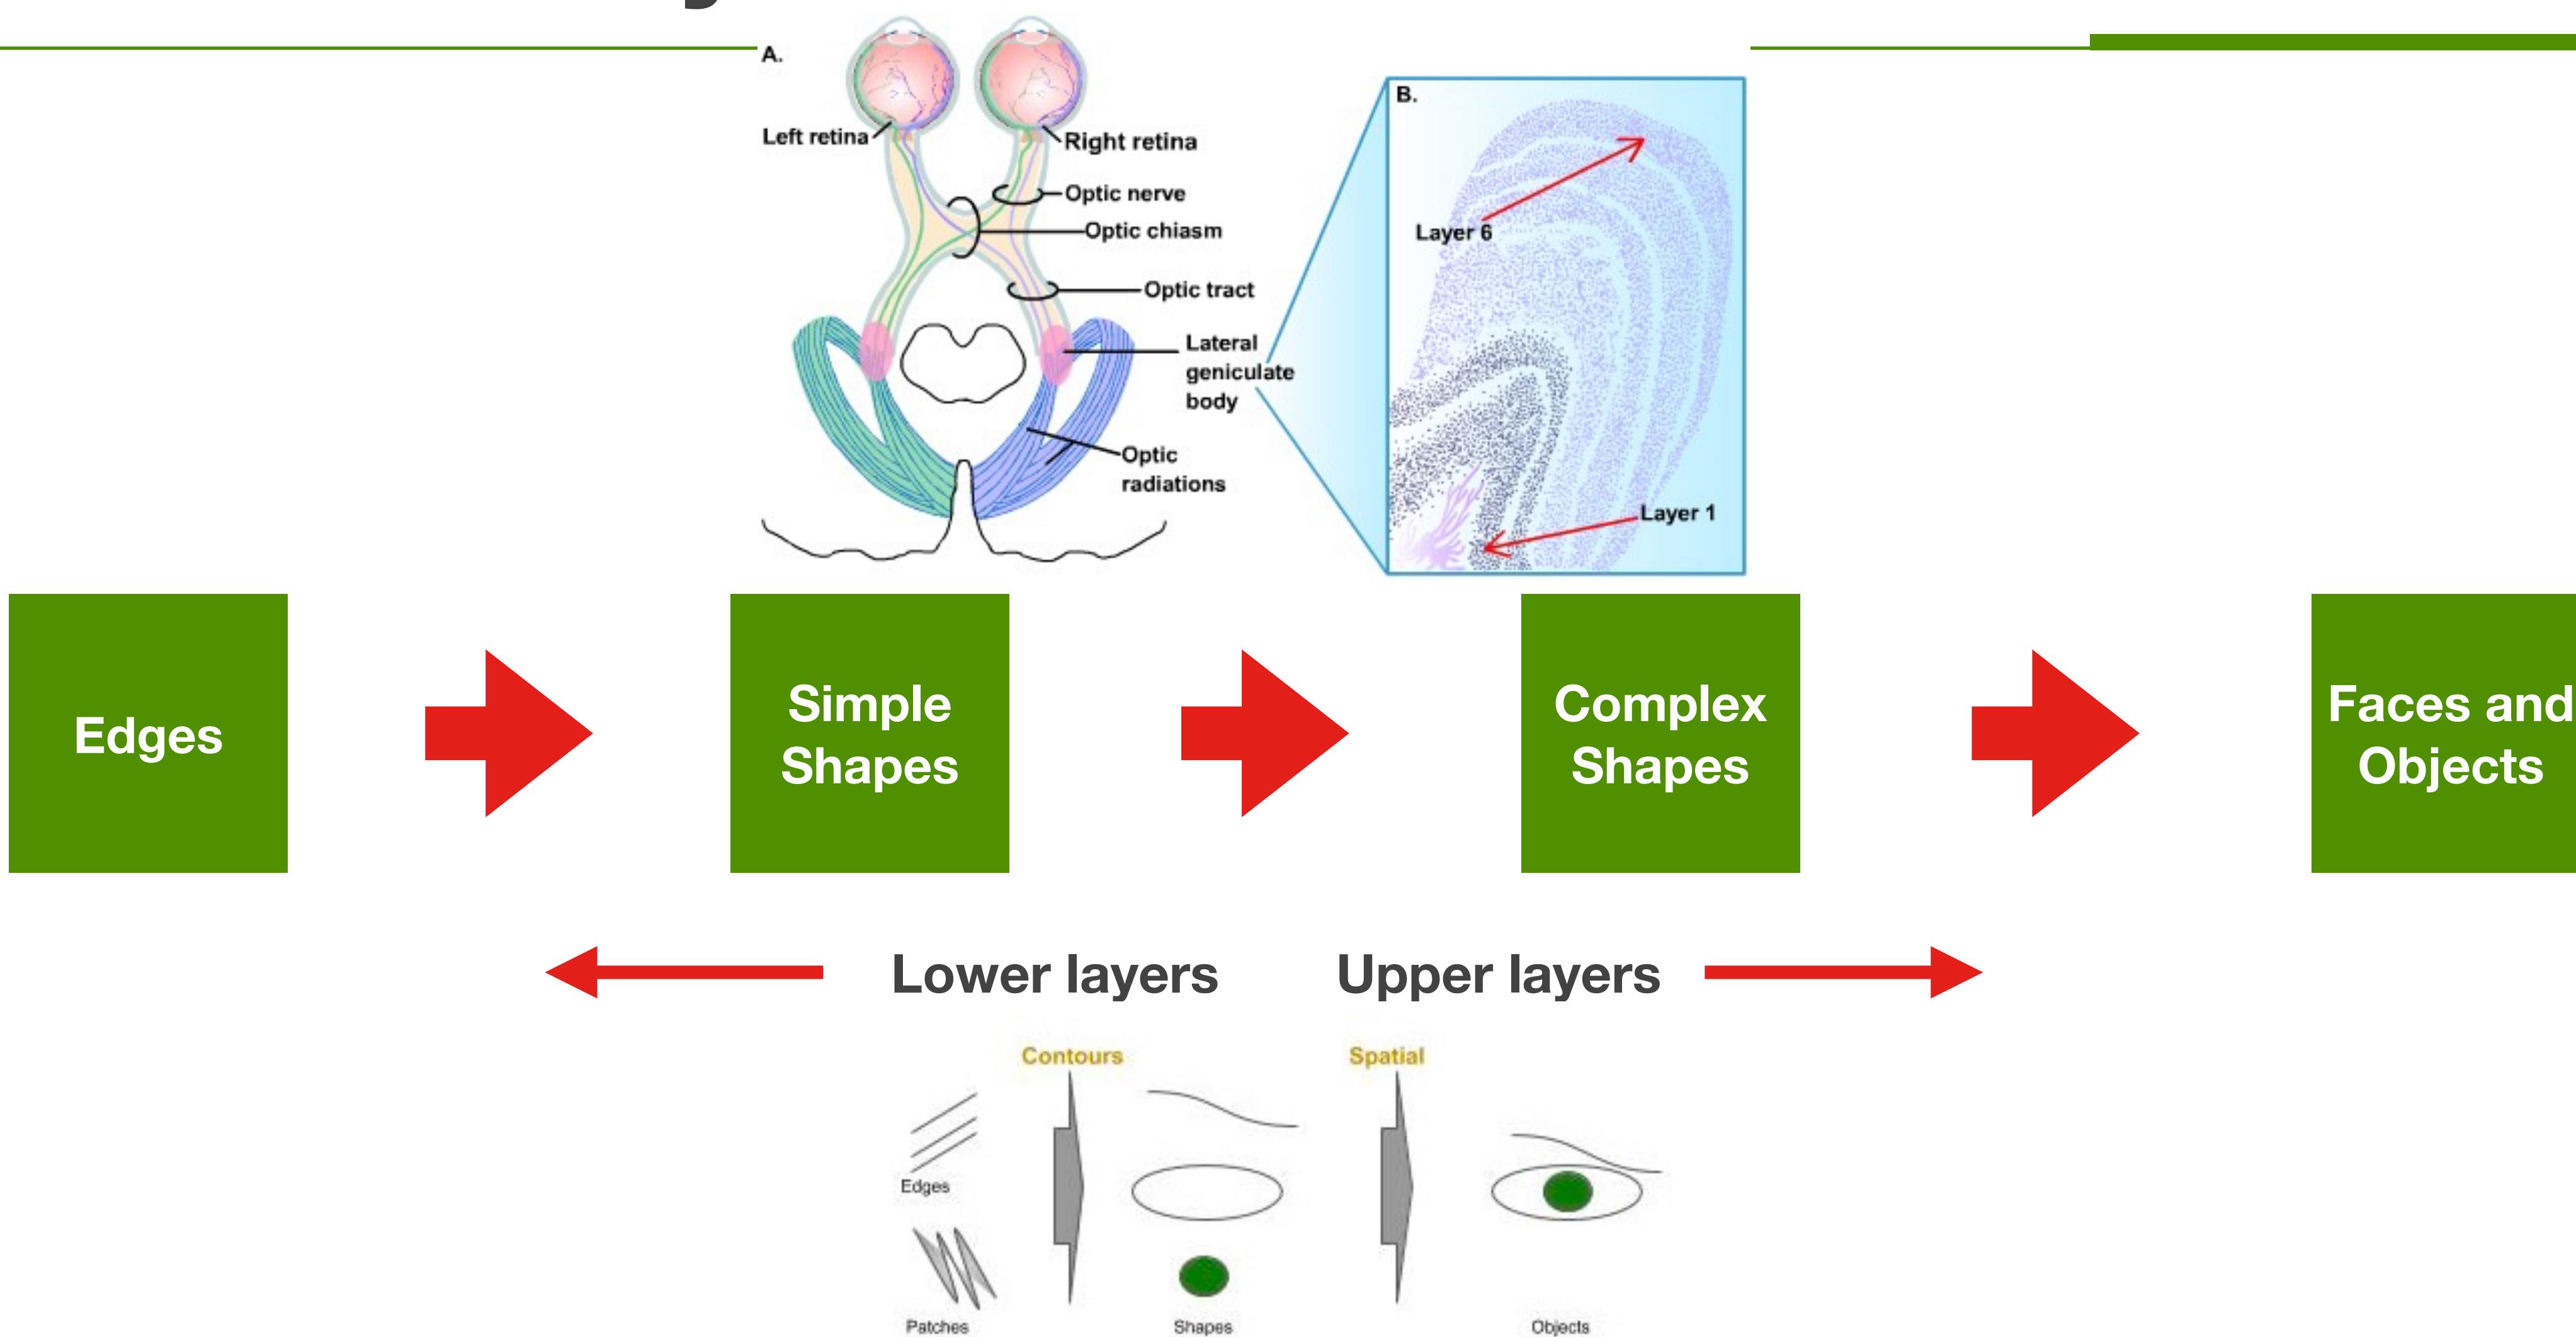

FIGURE 4.8 Response of a single cortical cell to bars presented at various orientations.

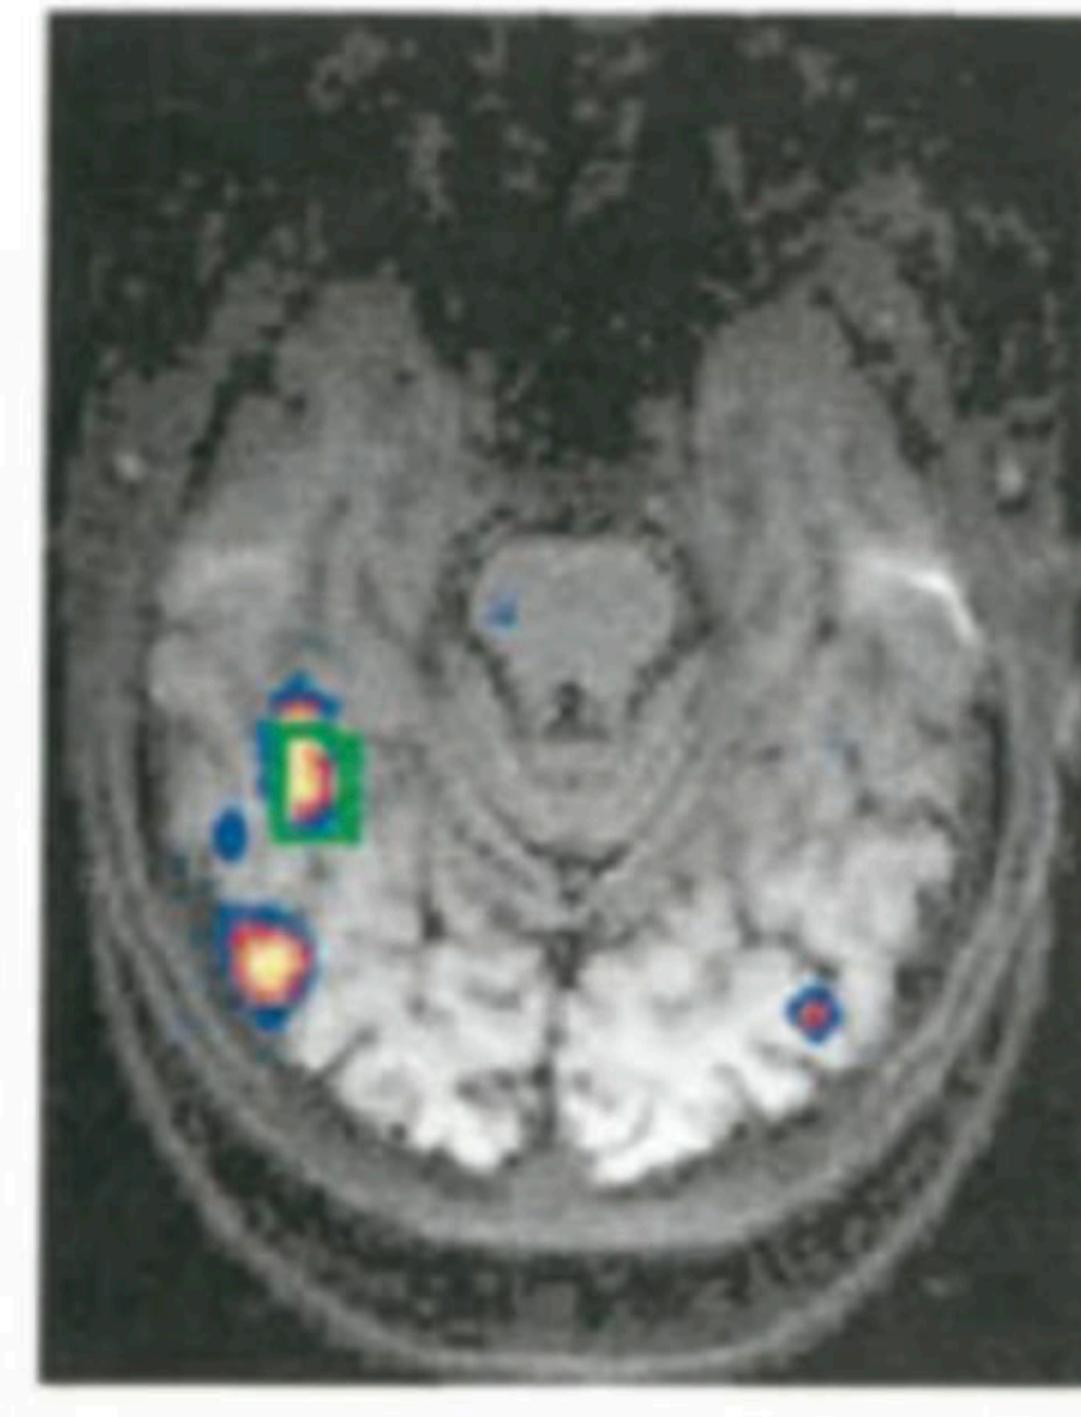

<https://www.youtube.com/watch?v=IOHayh06LJ4>

Neural Pathways

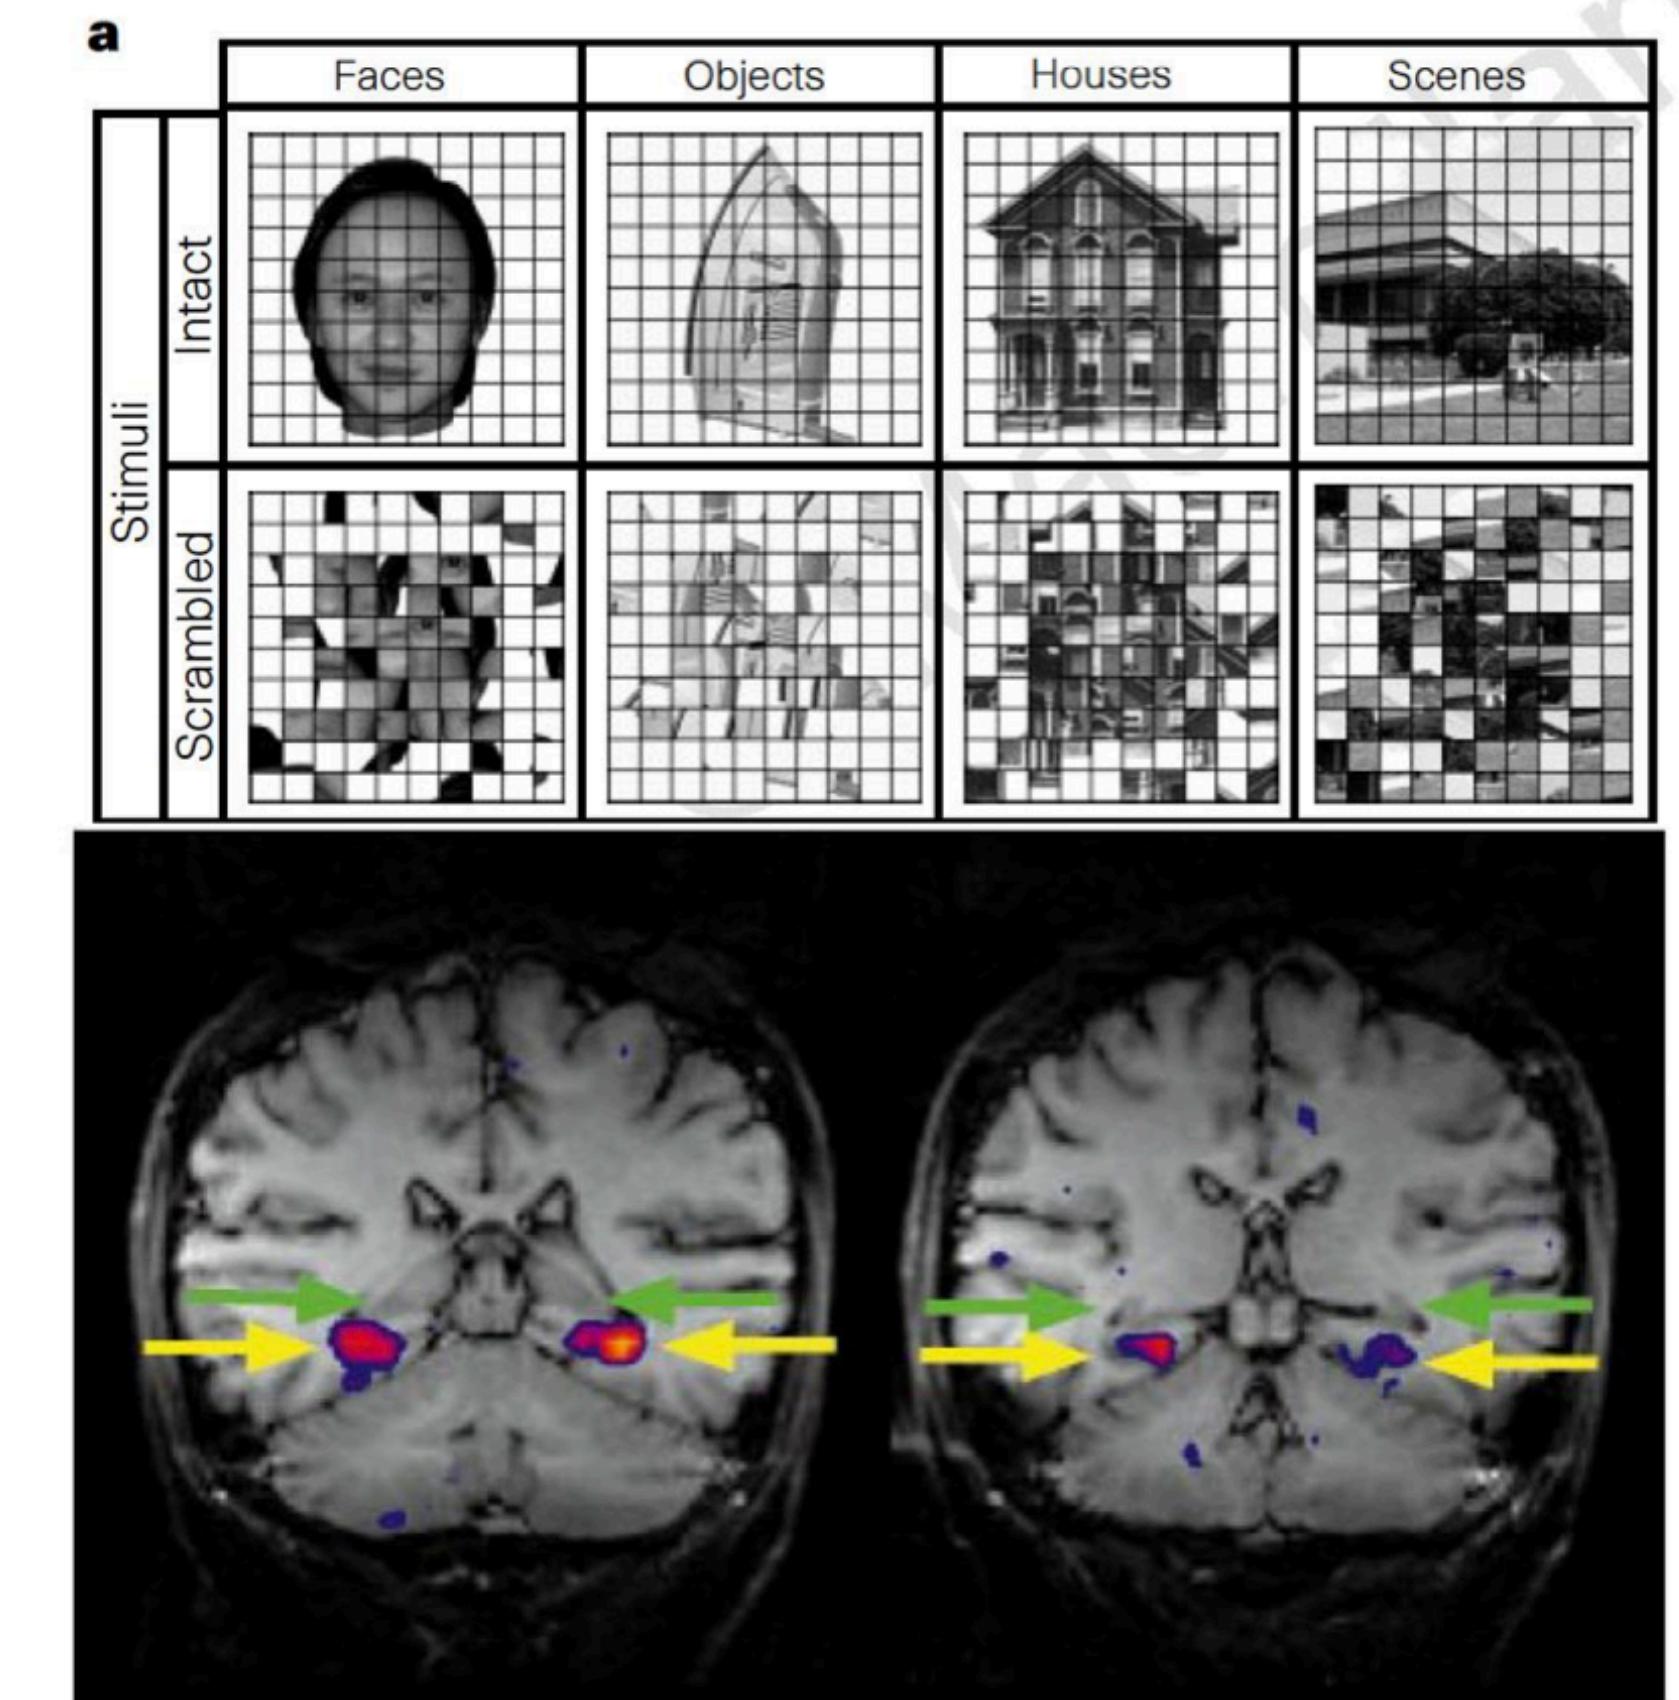

Neural Correlation of Objects & Scene Recognition

Faces > Houses

% signal change

Kanwisher et al. J. Neuro. 1997

Epstein & Kanwisher, Nature, 1998

Why is machine vision hard?

The deformable and truncated cat

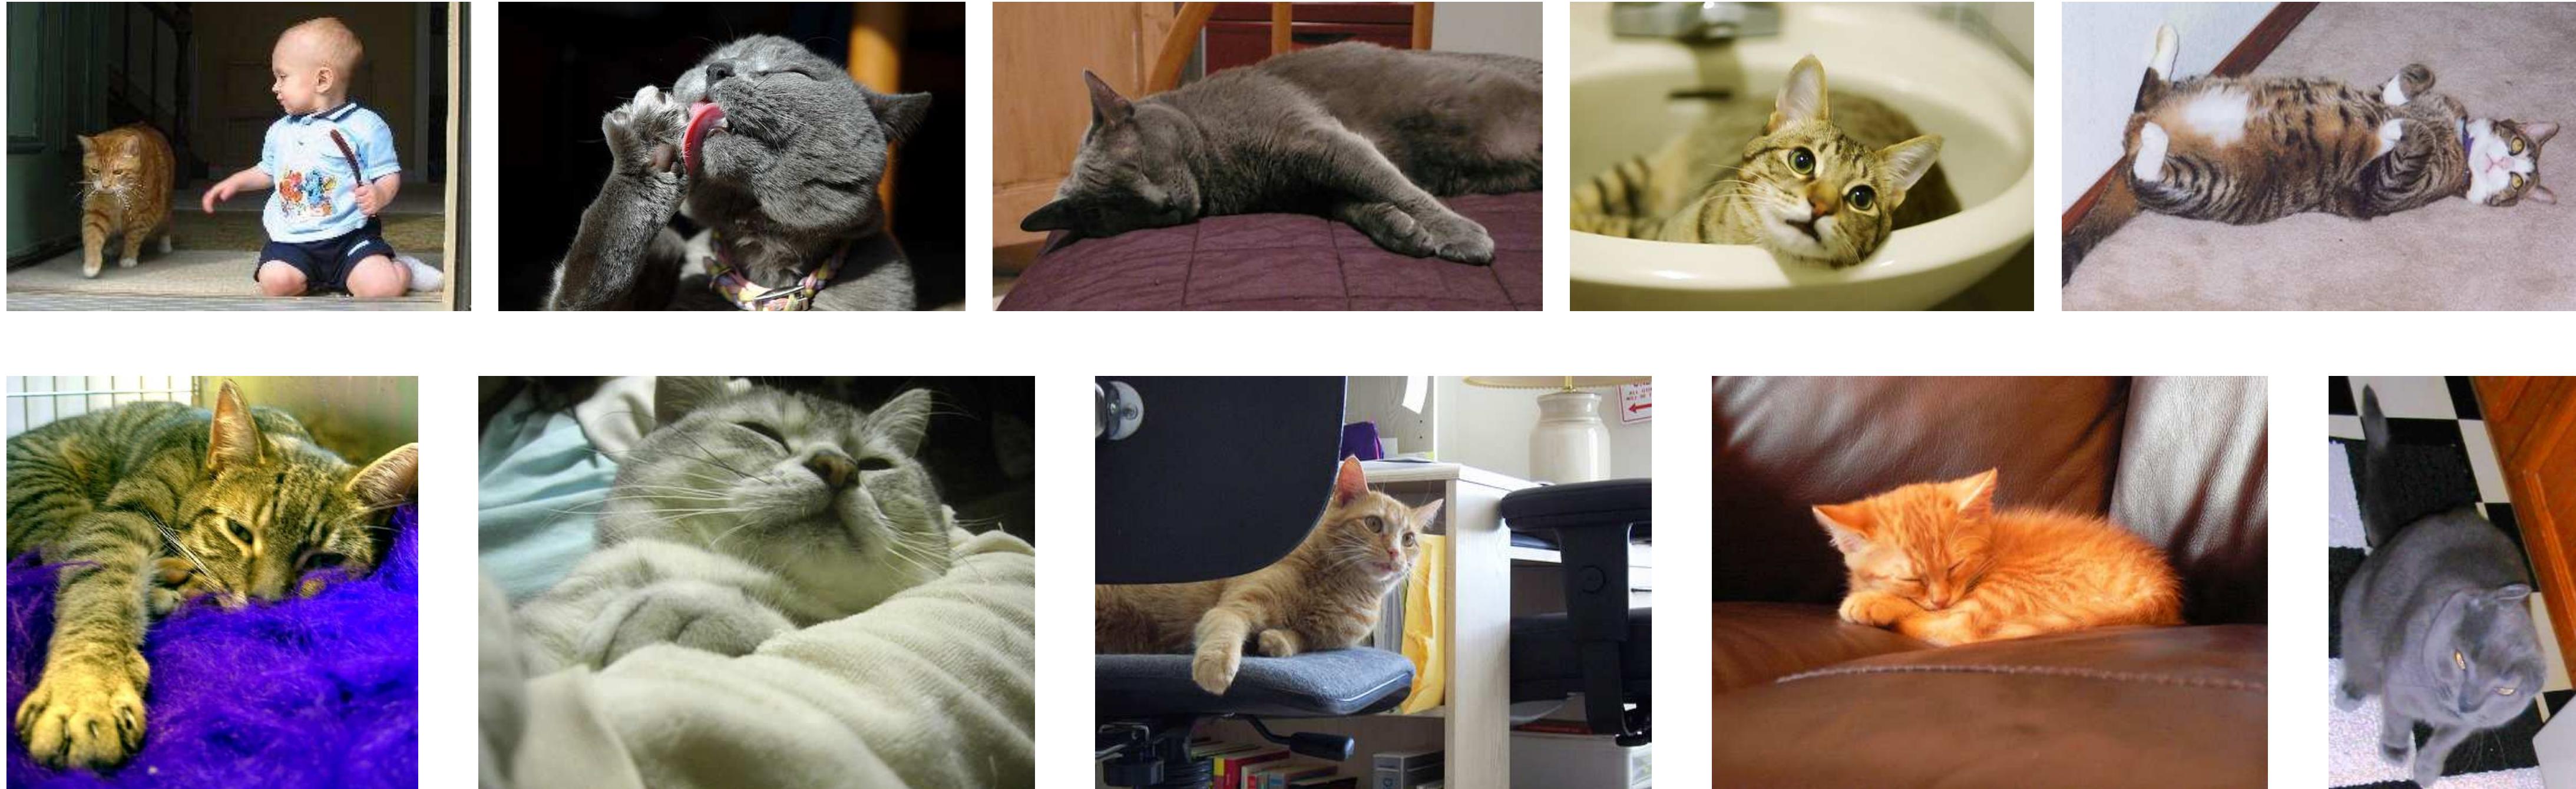

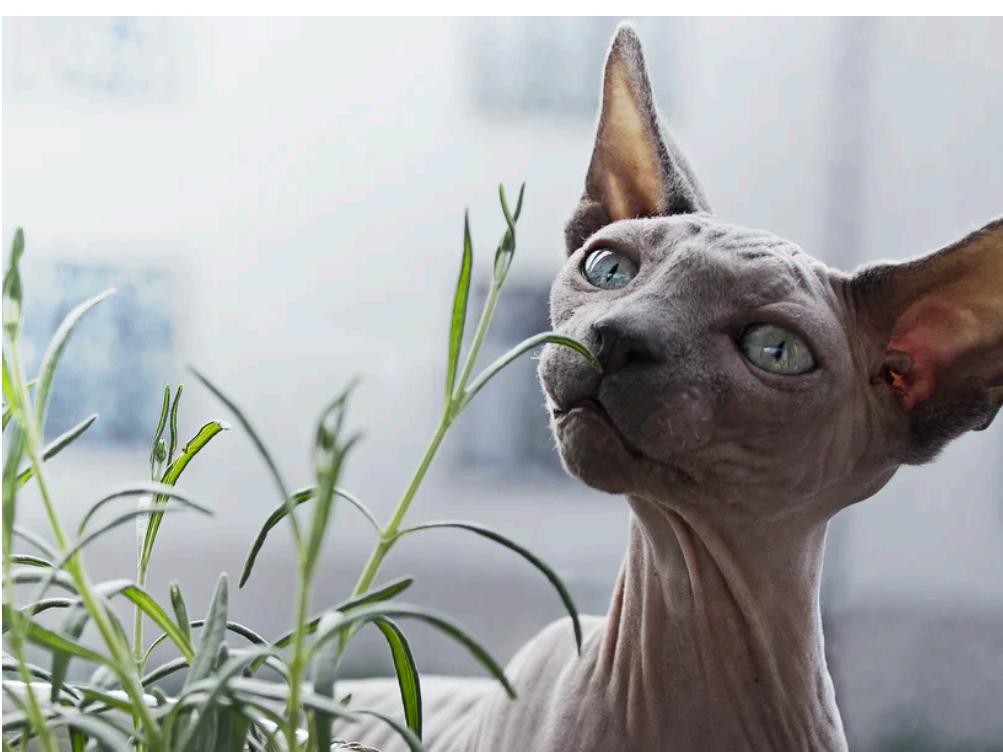

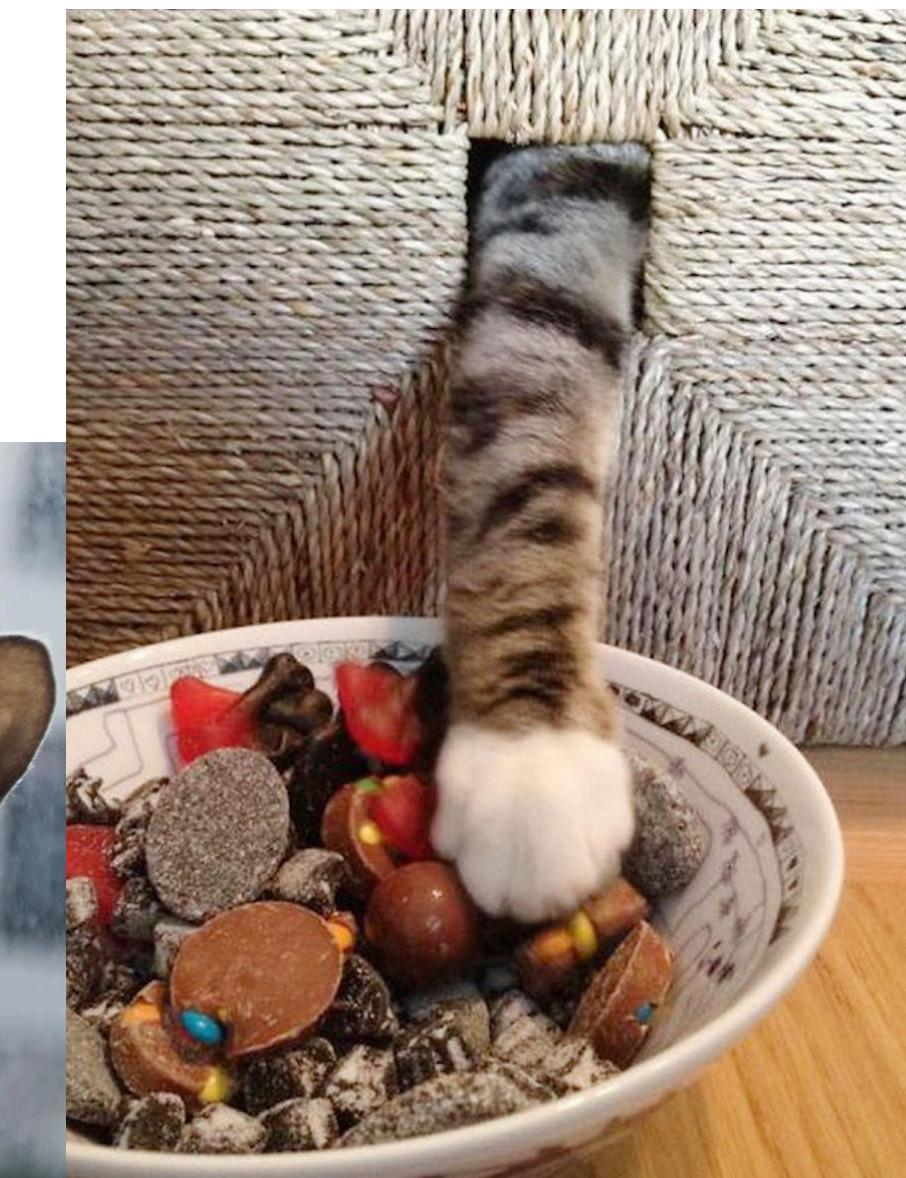

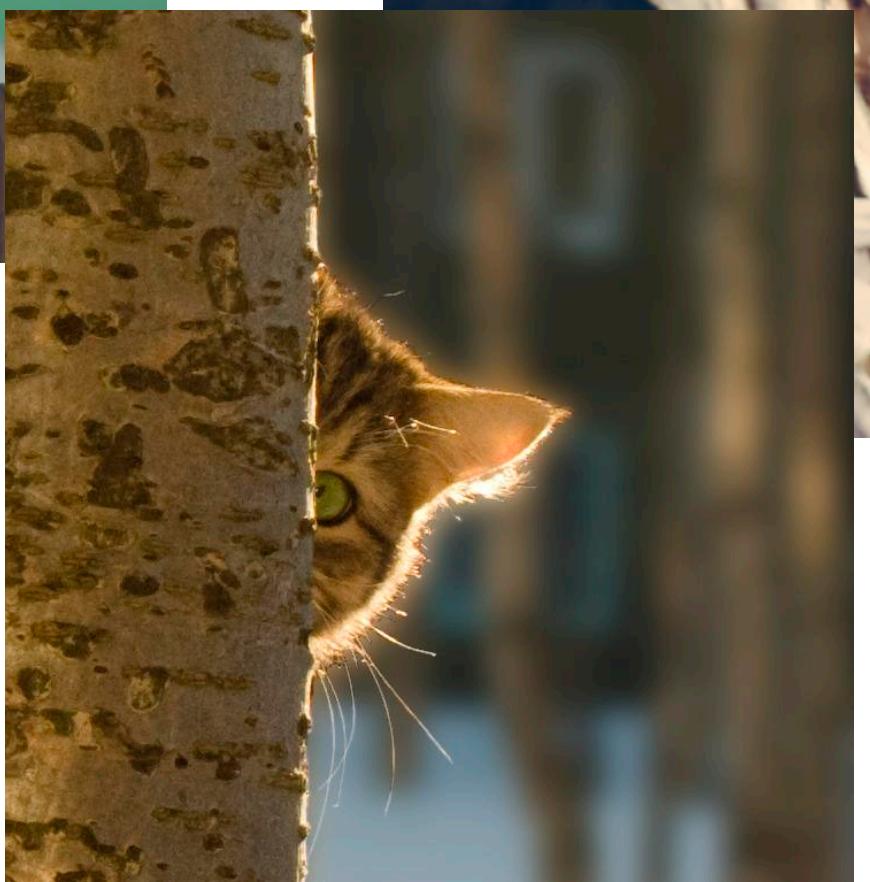

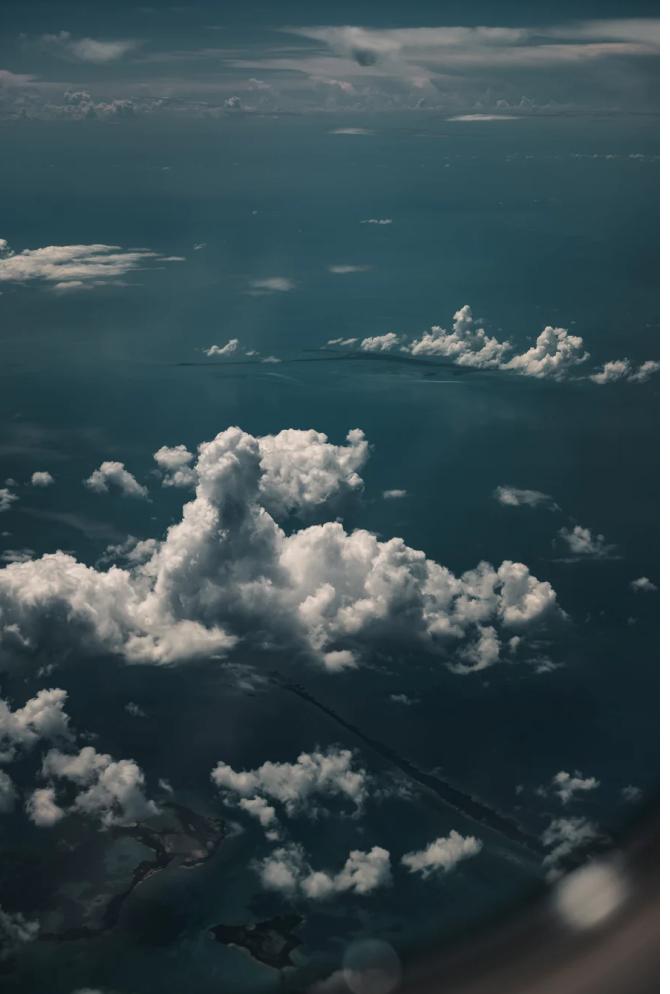

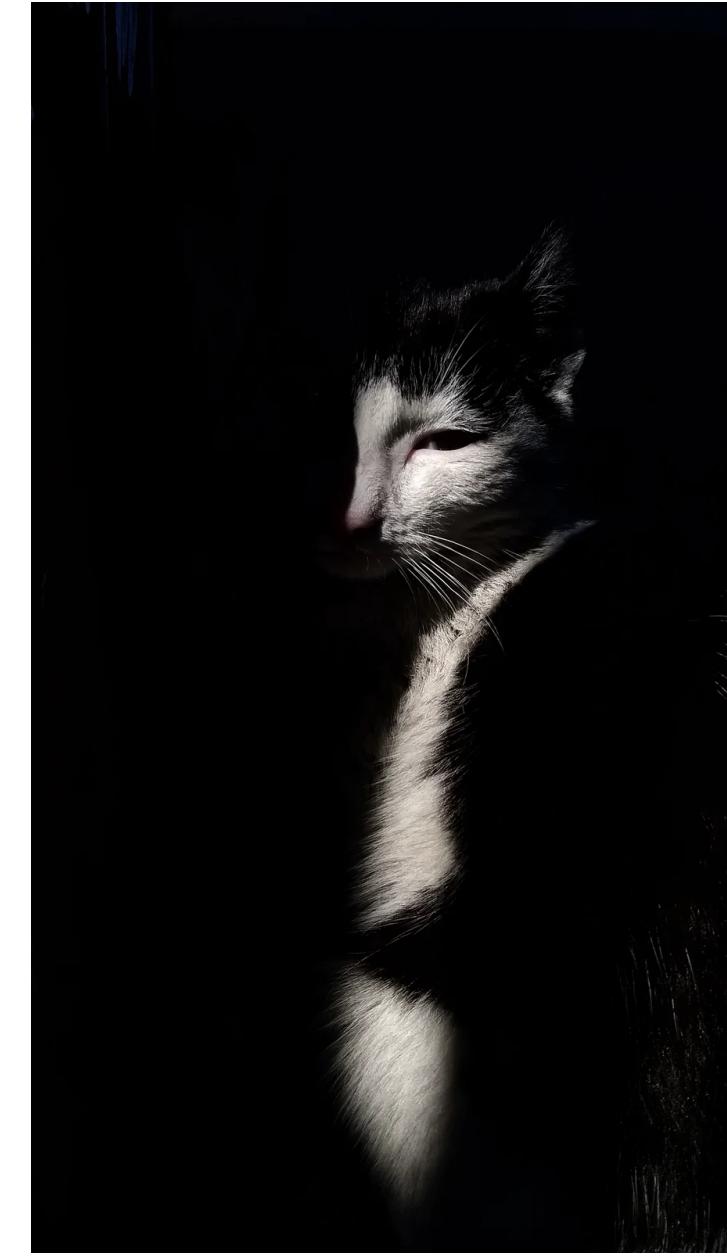

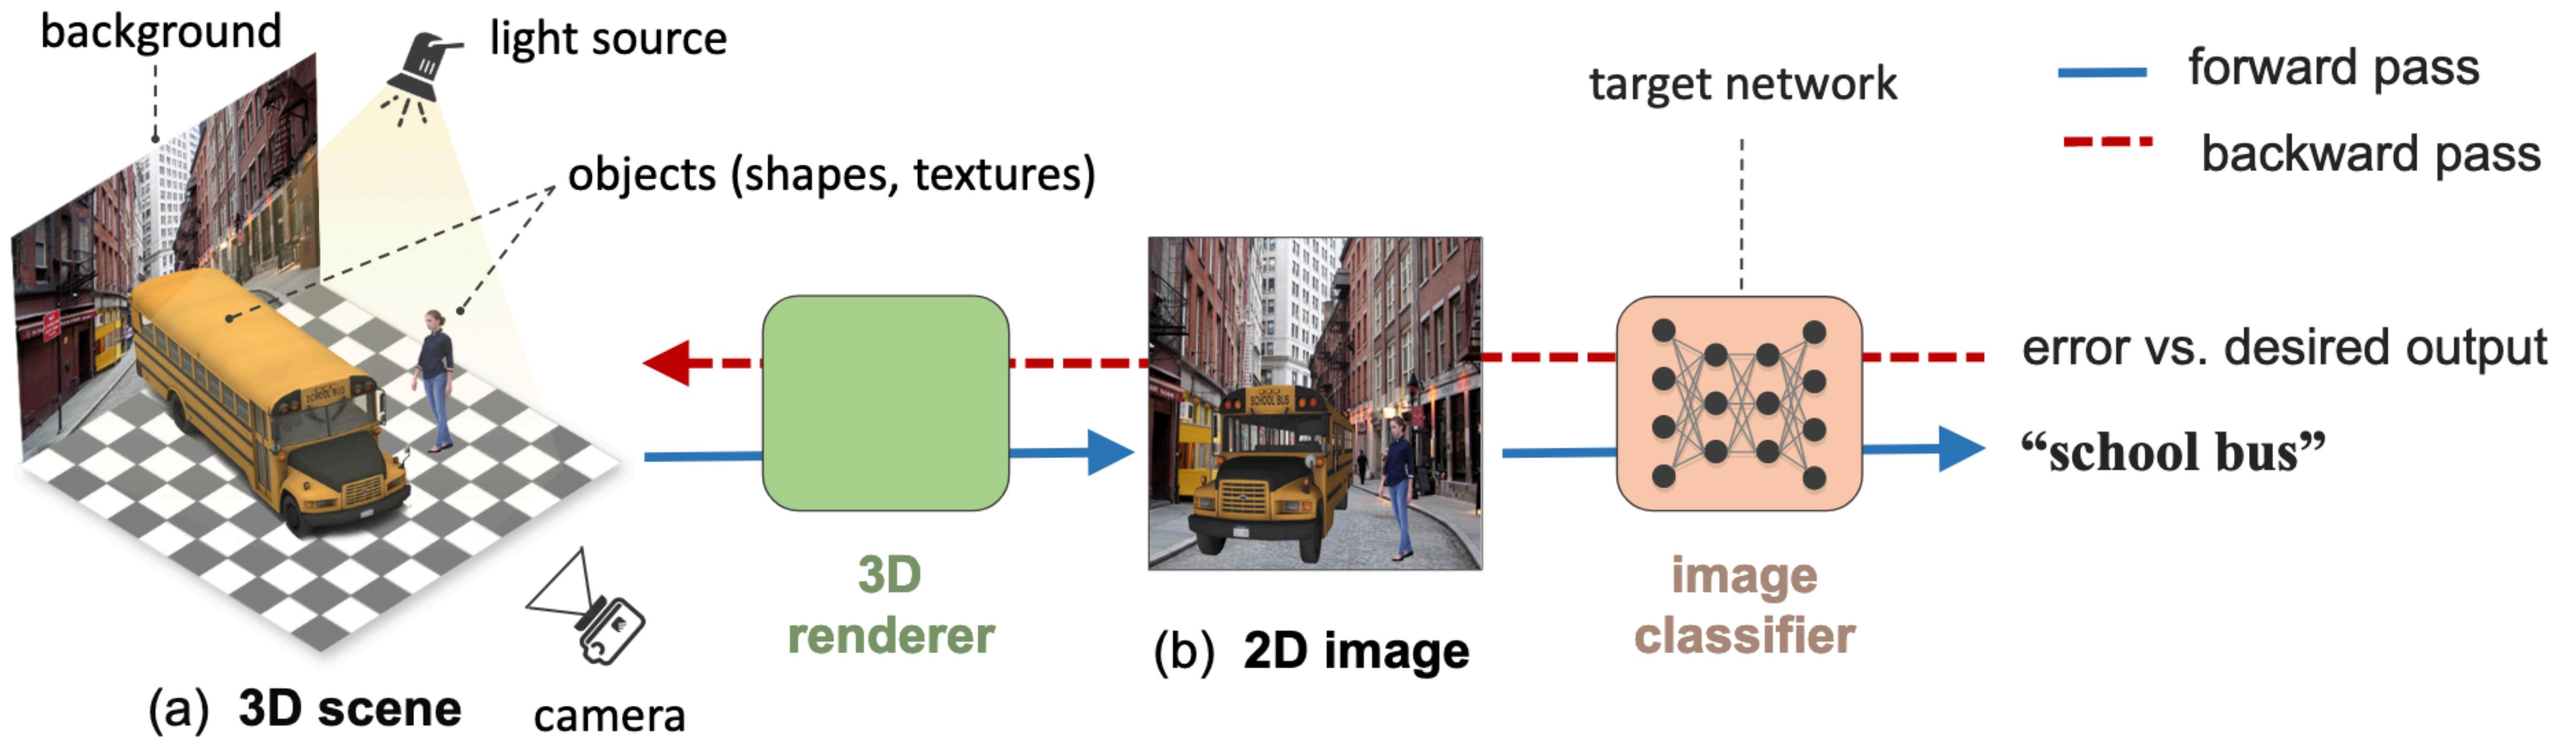

Figure 1. The deformable and truncated cat. Cats exhibit (almost) unconstrained variations in shape and layout.

Parkhi et al. *The truth about cats and dogs*. 2011

Strike (with) a Pose: Neural Networks Are Easily Fooled by Strange Poses of Familiar Objects. Alcorn et al. 2019

Computer Vision Challenges

■ Viewpoint Variation

- A single instance of an object can be oriented in many ways with respect to the camera

■ Scale variation

- Visual classes often exhibit variation in their size (size in the real world, not only in terms of their extent in the image)

■ Deformation

- Many objects of interest are not rigid bodies and can be deformed in extreme ways

■ Occlusion

- The objects of interest can be occluded. Sometimes only a small portion of an object (as little as few pixels) could be visible

■ Illumination Condition

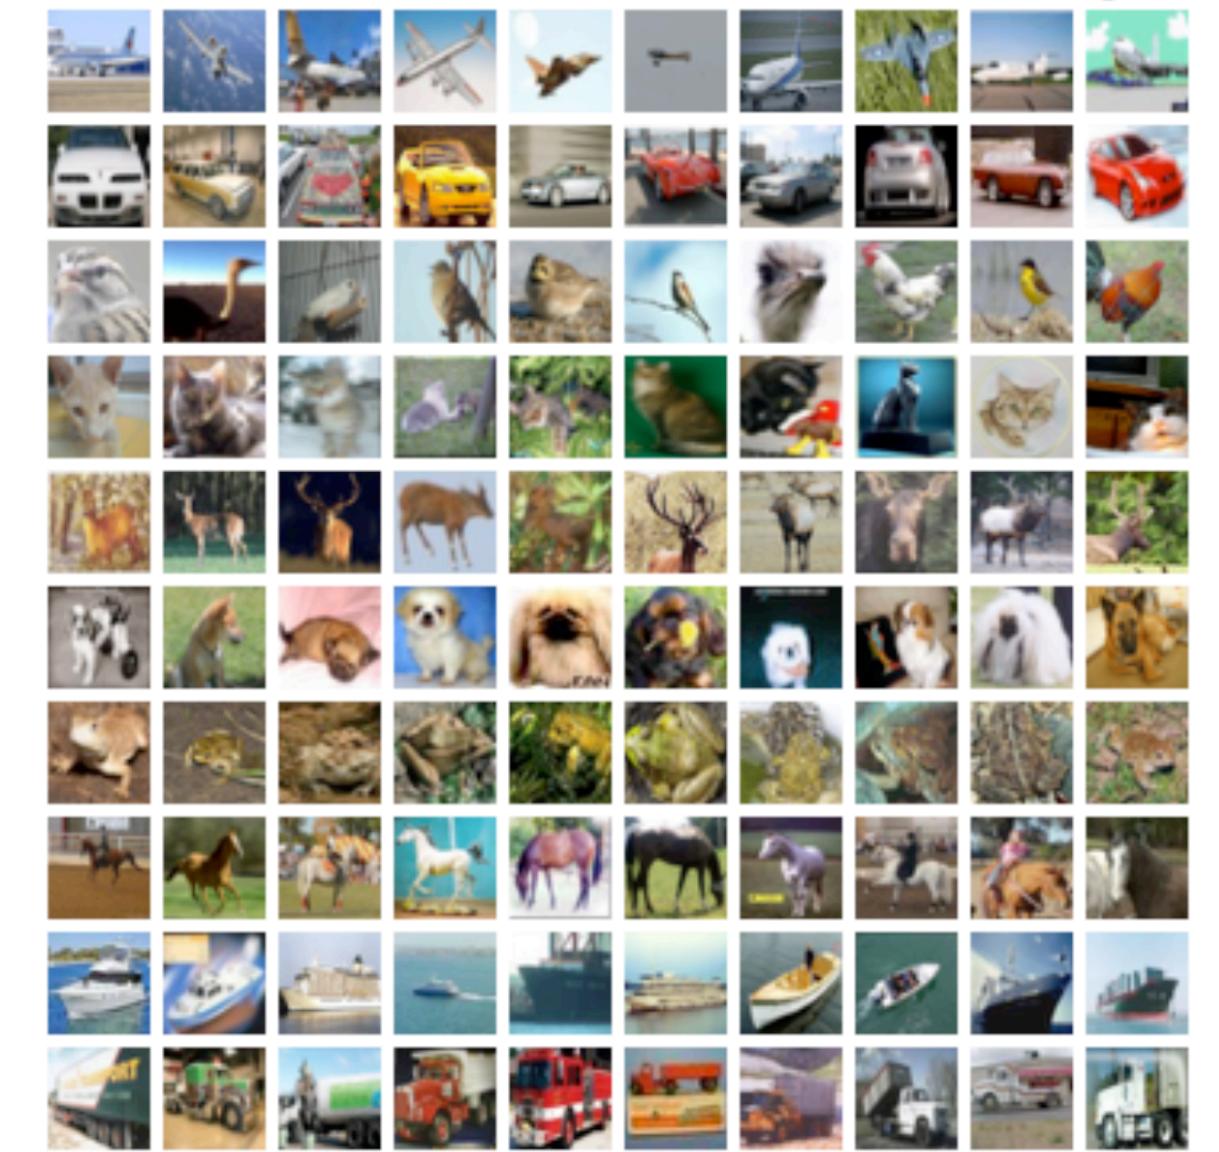

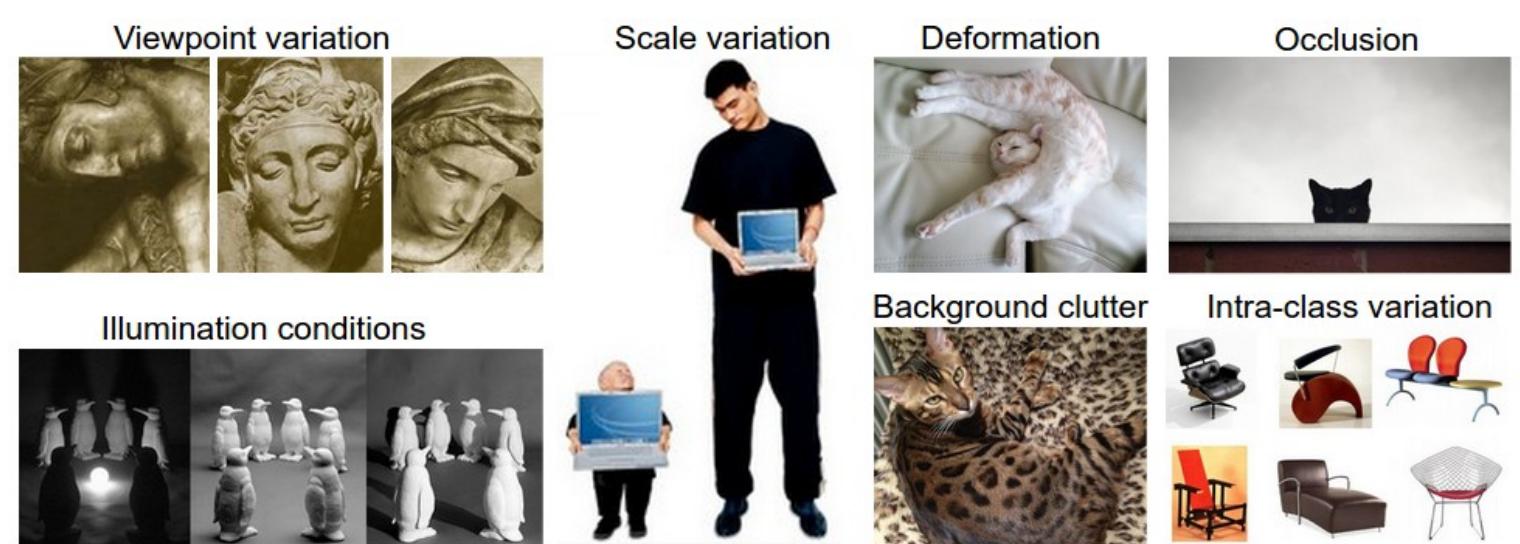

- The effects of illumination are drastic on the pixel level

■ Background clutter

- The objects of interest may blend into their environment, making them hard to identify

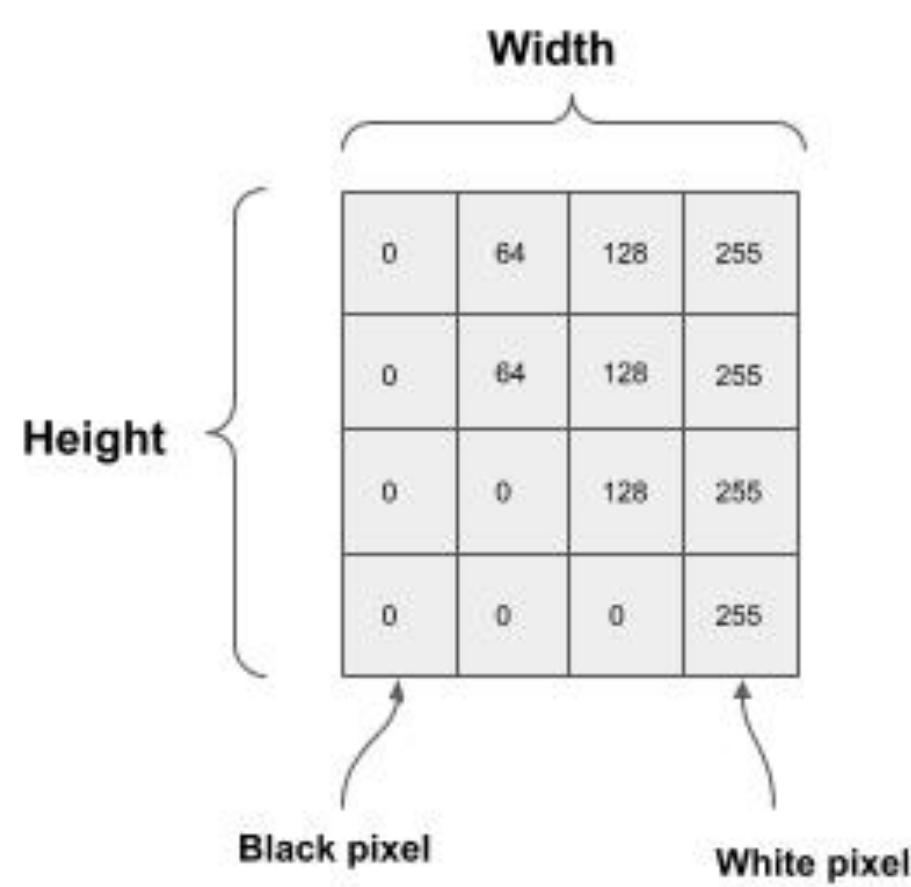

■ Intra-class variation

- The classes of interest can often be relatively broad, such as chair. There are many different types of these objects, each with their own appearance

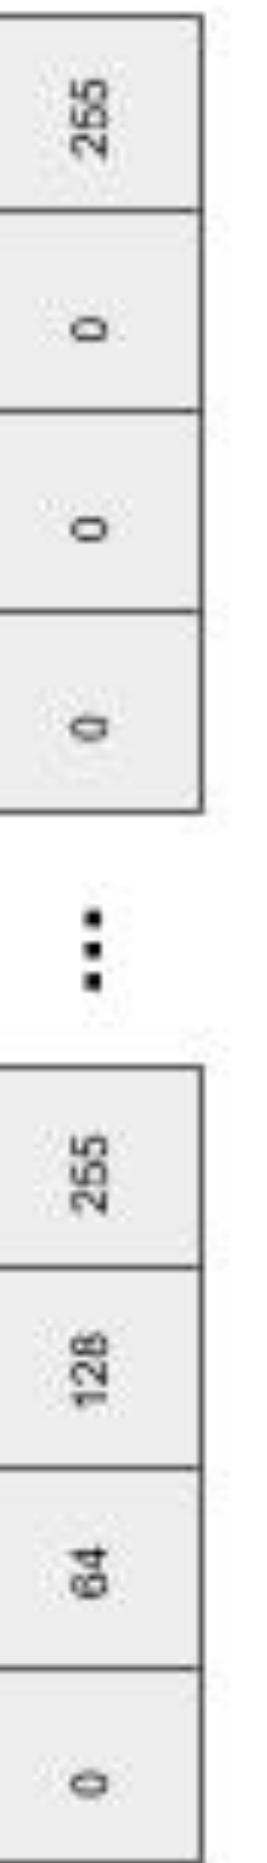

How CV models work?

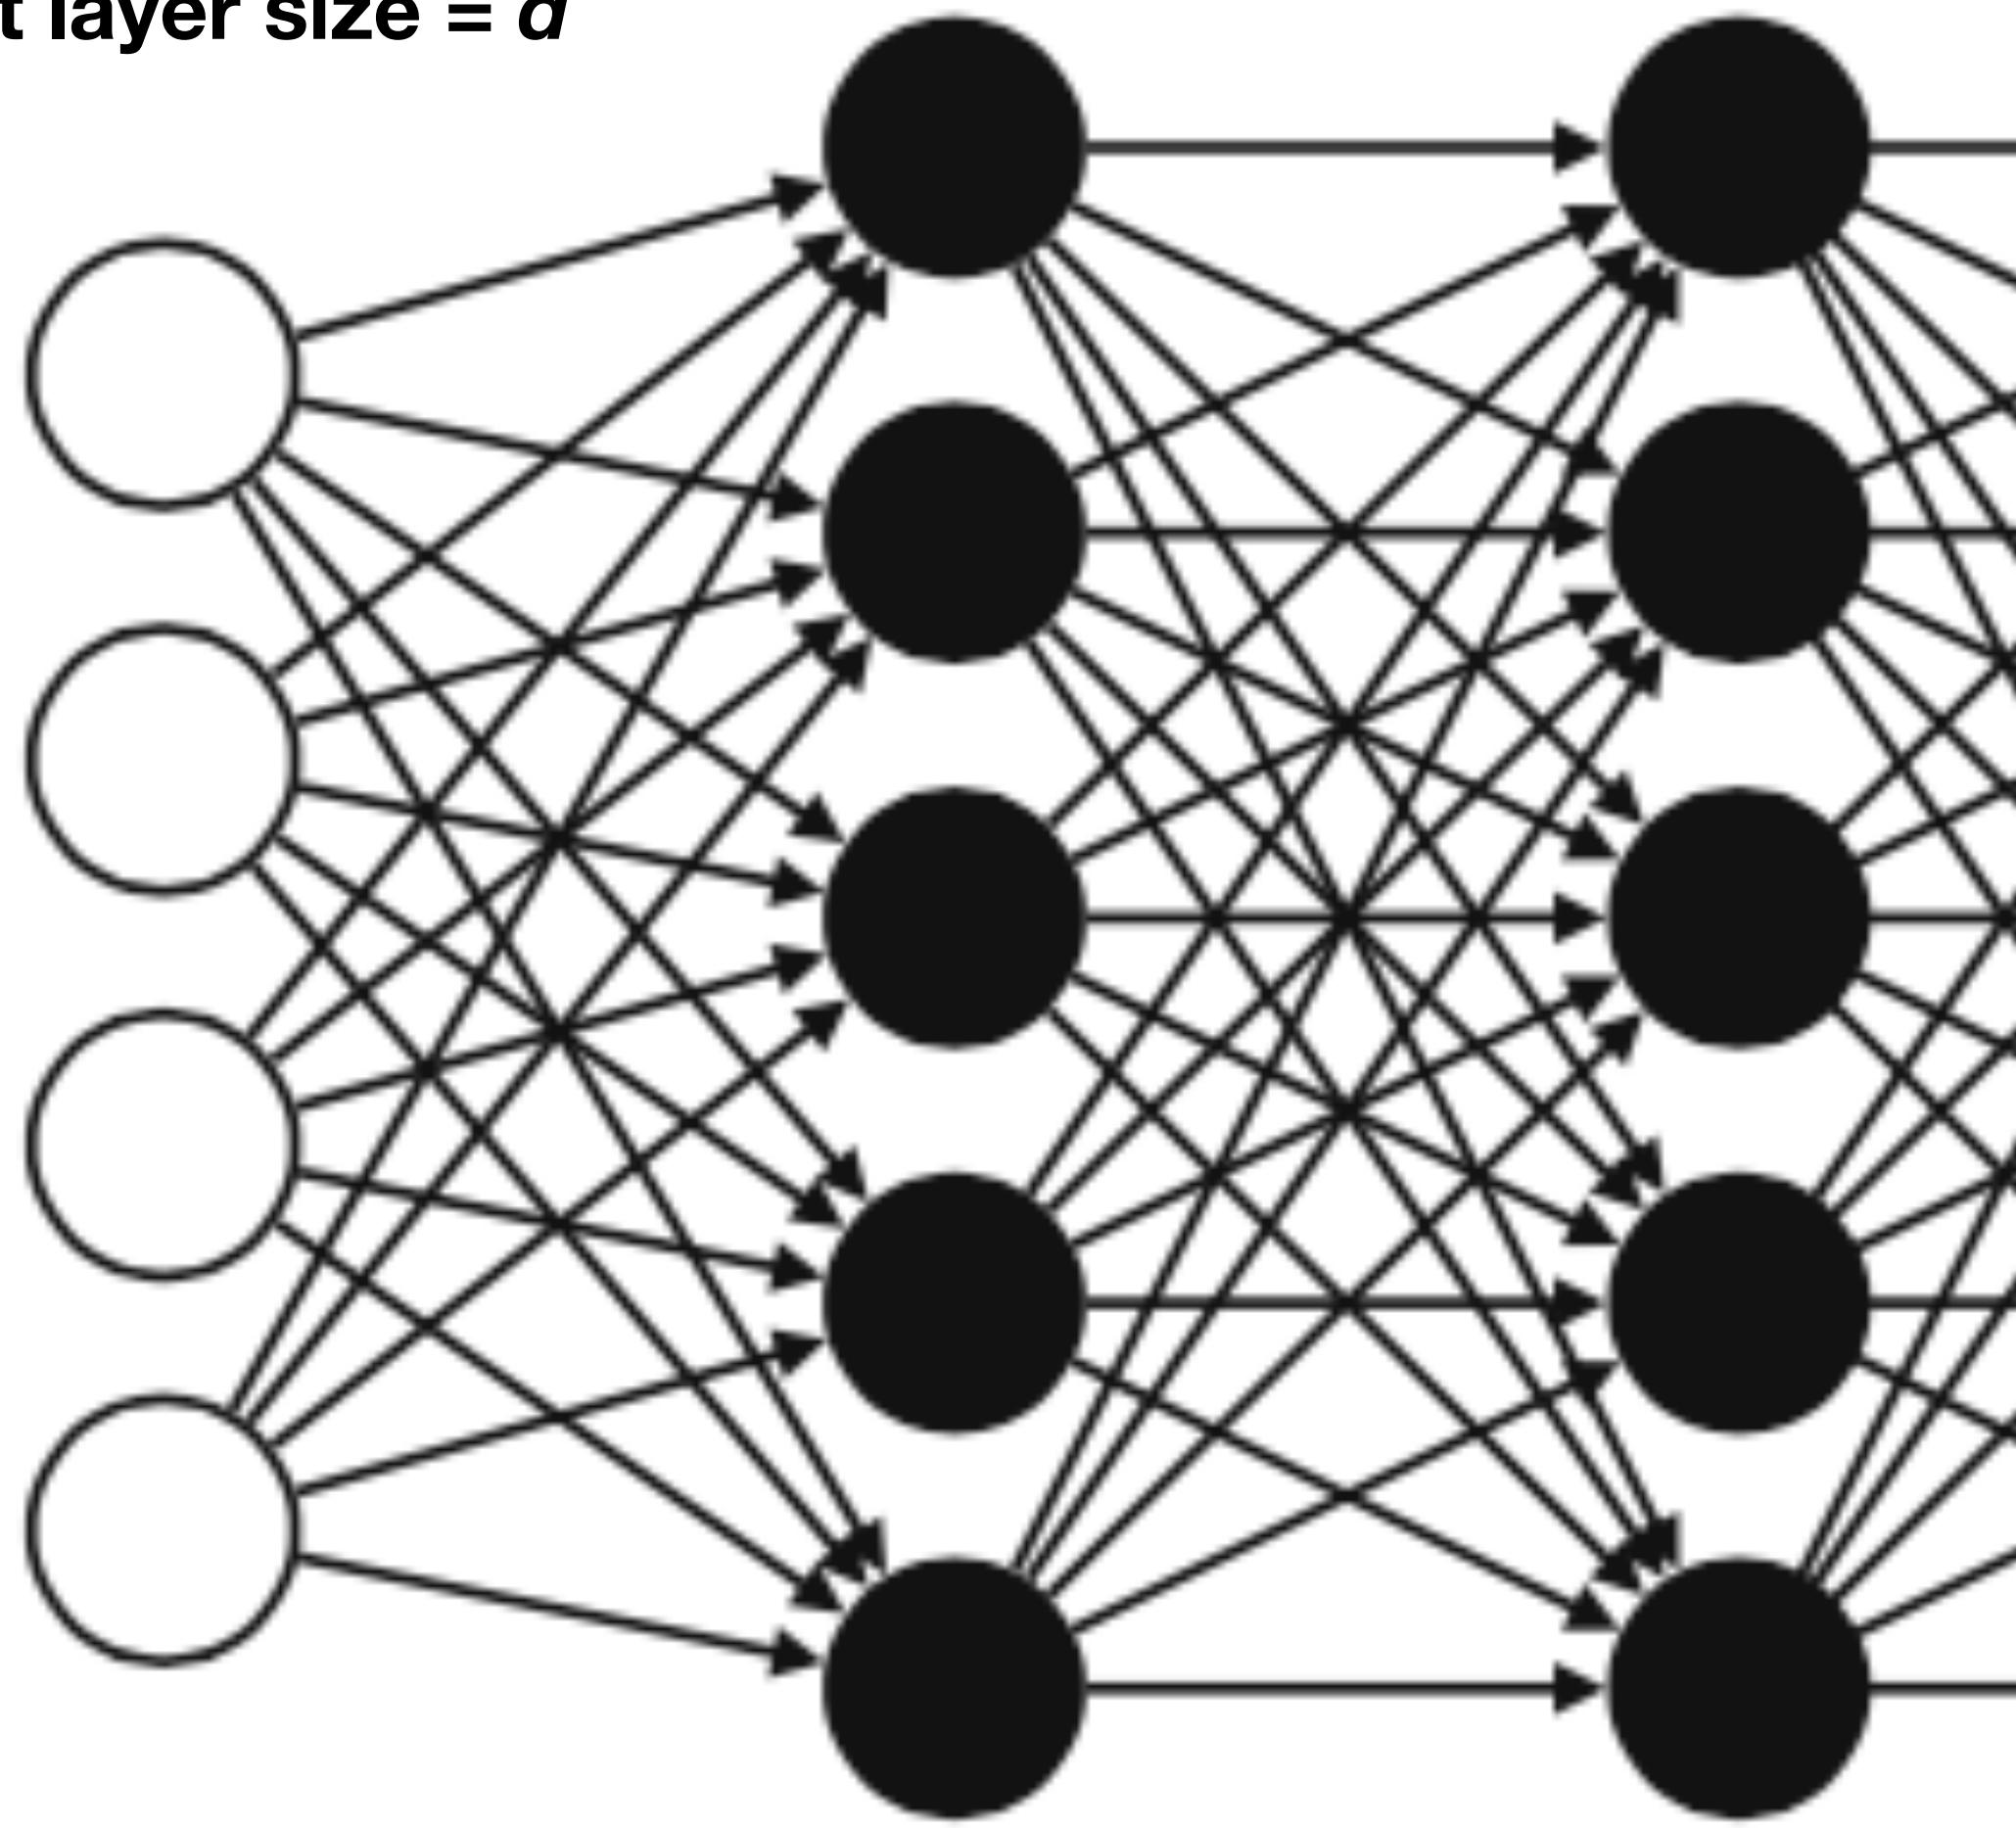

Flattening

$$d = \text{width} \times \text{height}$$

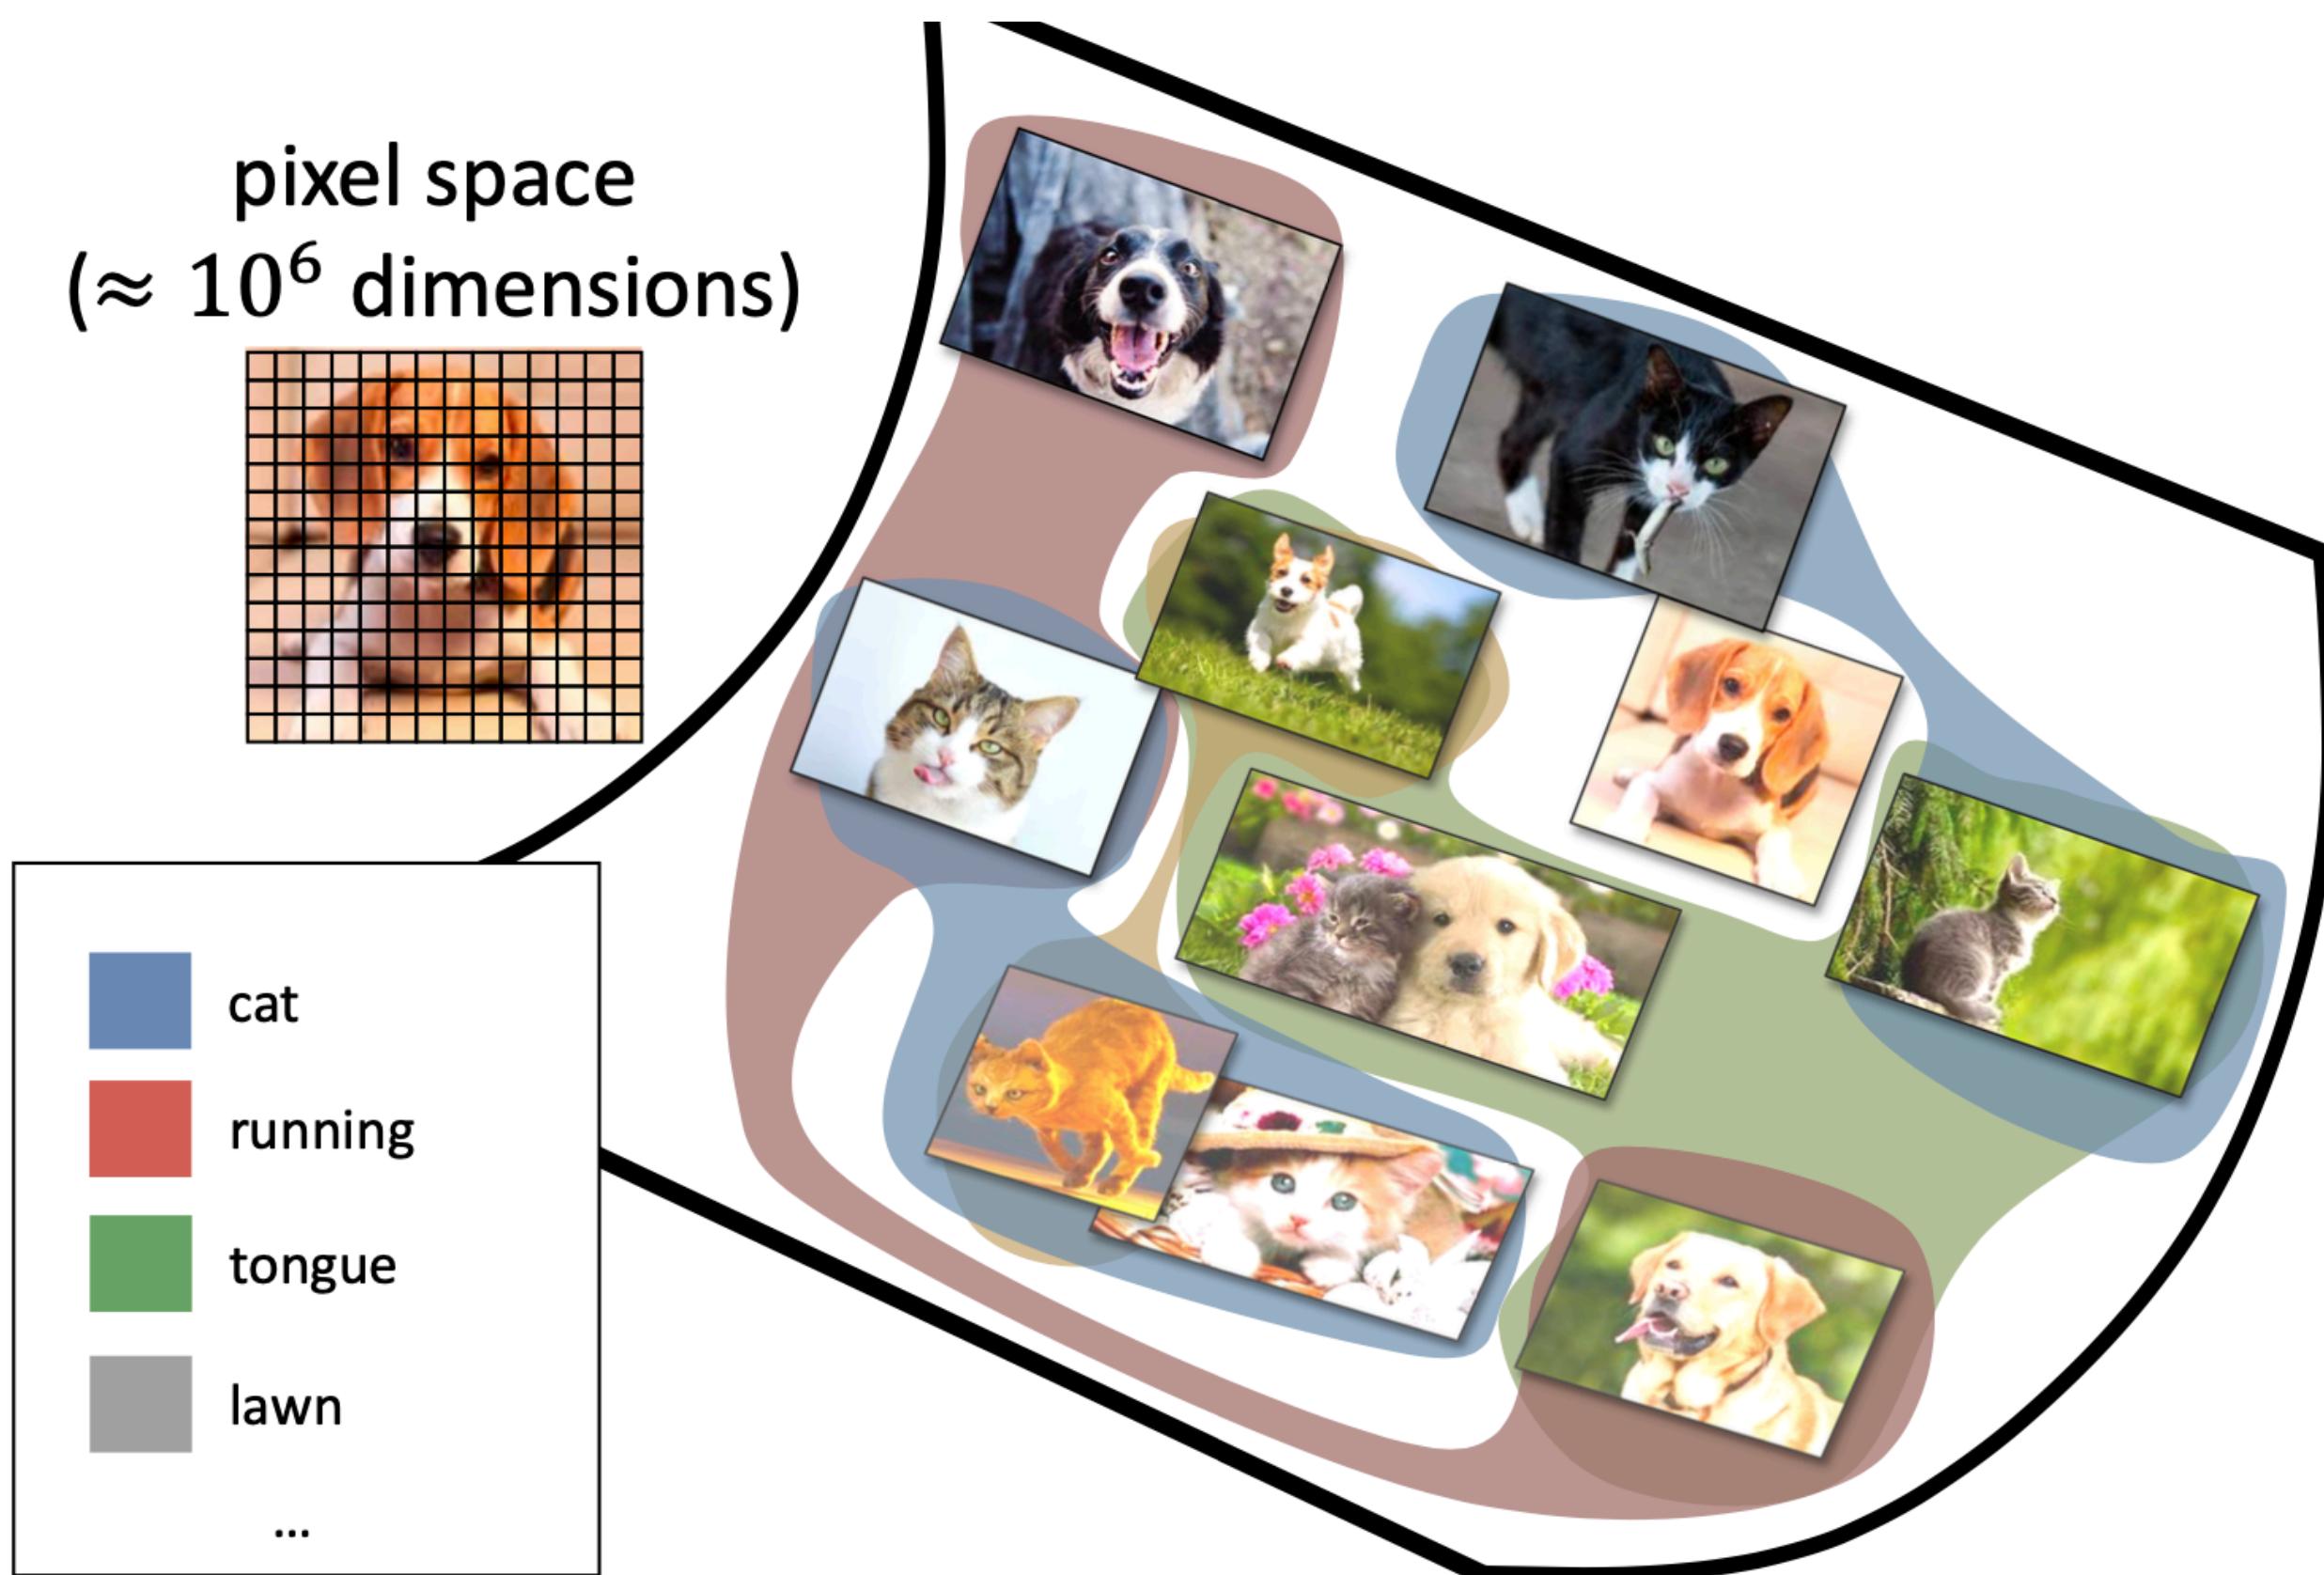

Input layer size = d

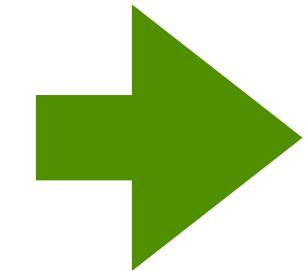

Course of dimensionality

- High dimensionality
 - A 1024×768 image has $d = 786432!$
 - A tiny 32×32 image has $d = 1024$
- Decision boundaries in pixel space are extremely complex
- We will need “big” ML models with lots of parameters
 - For example, linear regressors need d parameters

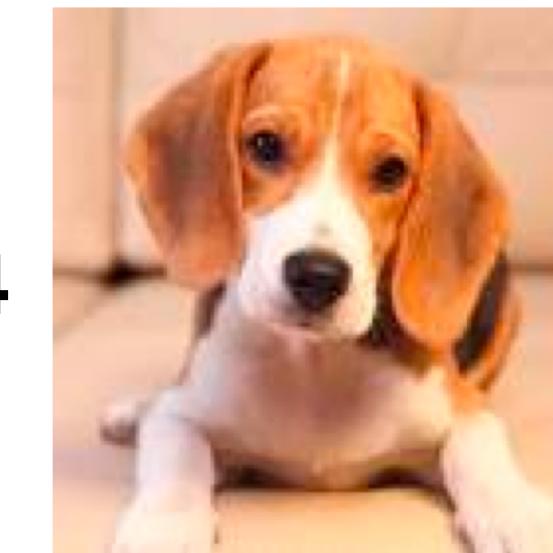

Downsampling

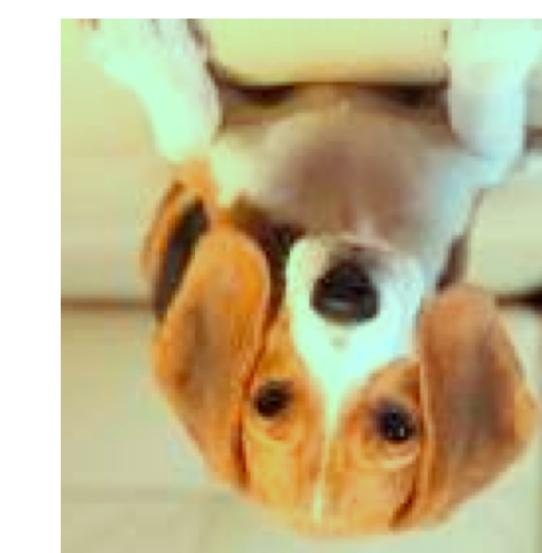

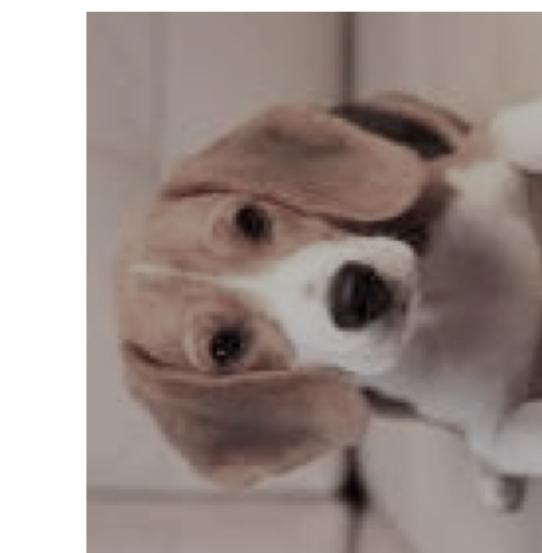

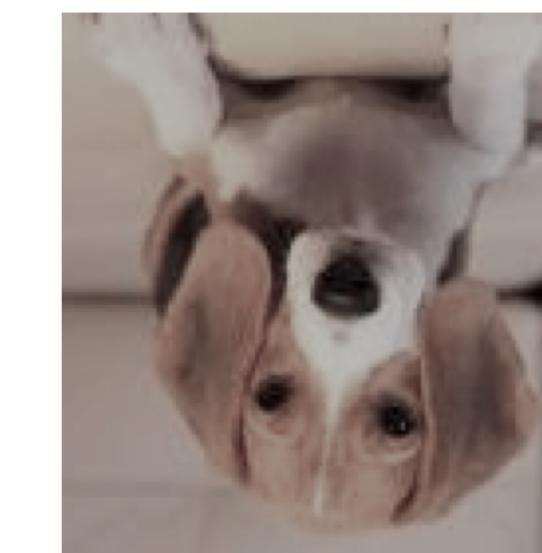

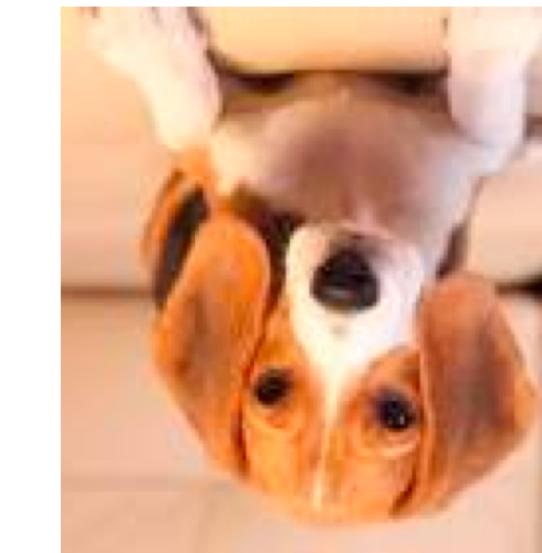

1024
1024

224
224

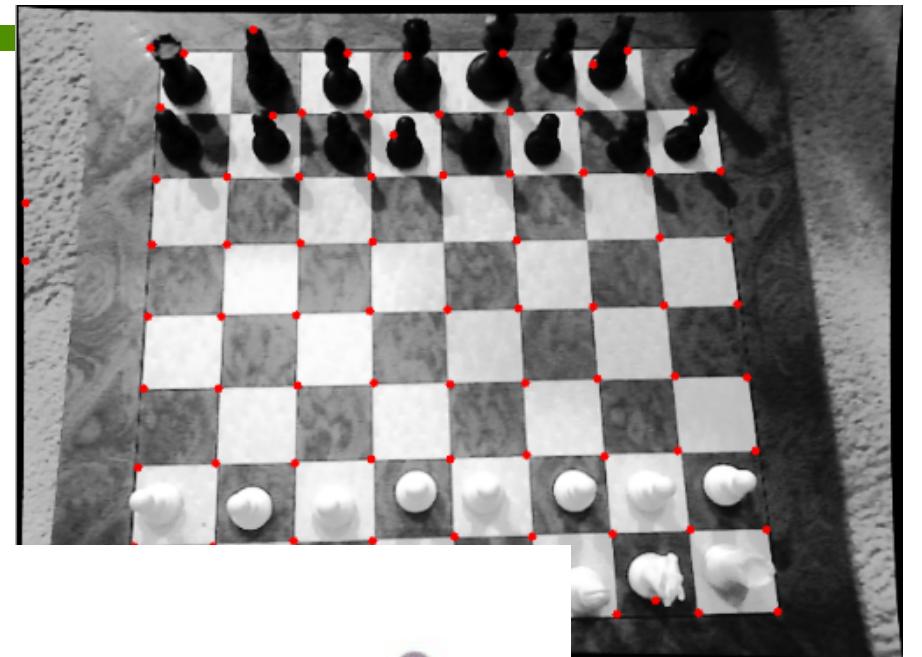

What about generalisation?

The “old days”: Feature Extraction

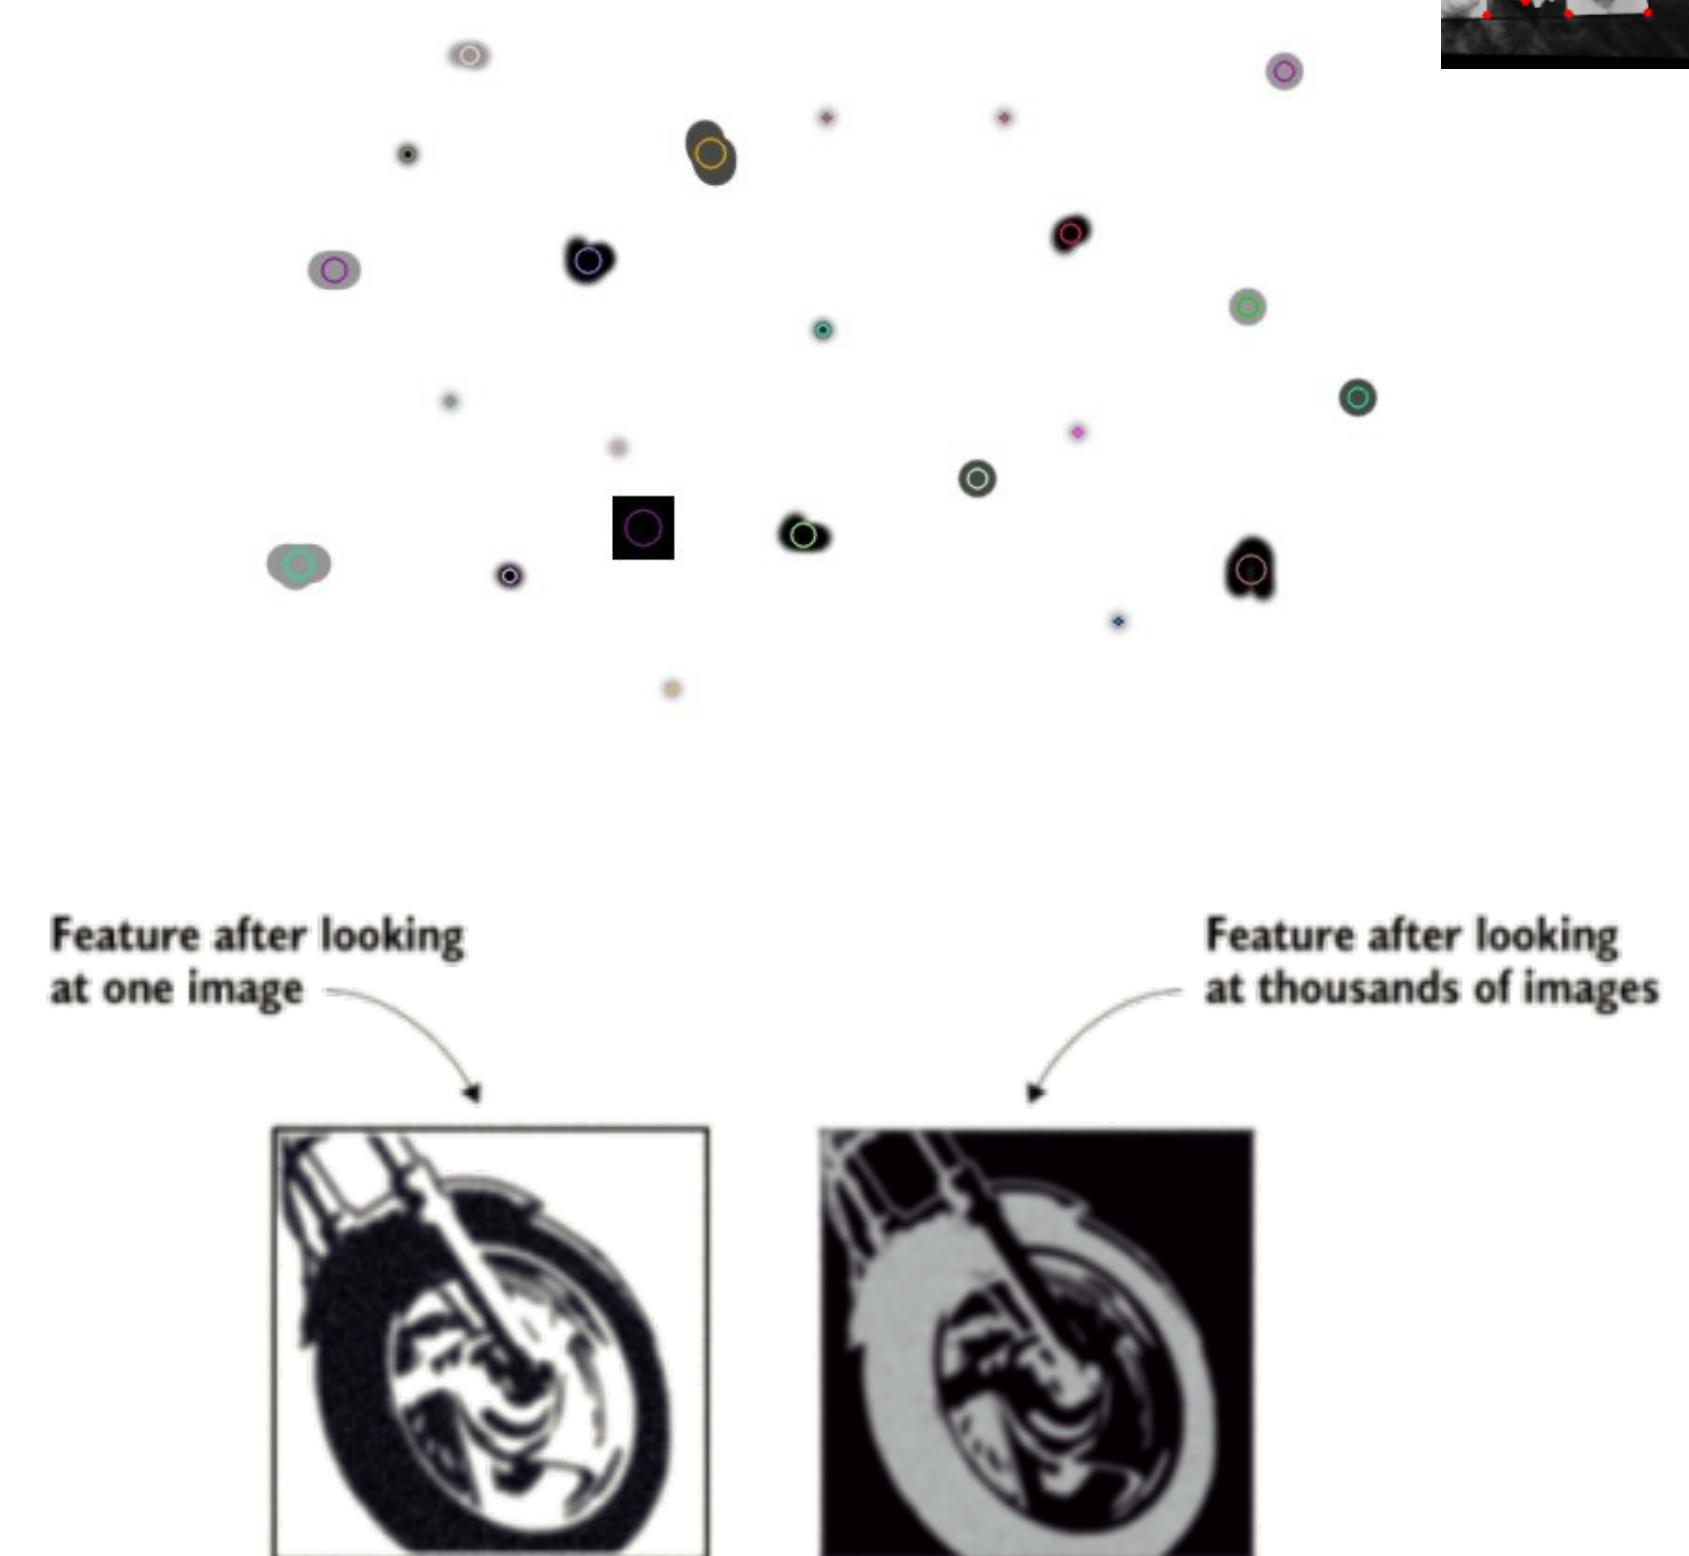

■ Feature

- A relevant piece of information about the content of an image
 - e.g. edges, corners, blobs (regions), ridges

■ A good feature

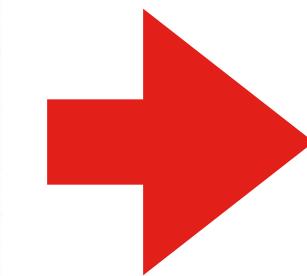

- Is repeatable
- Identifiable
- can be easily tracked and compared
- Is consistent across different scales, lighting conditions, and viewing angles
- Is still visible in noisy images or when only part of an object is visible
- can distinguish objects from one another

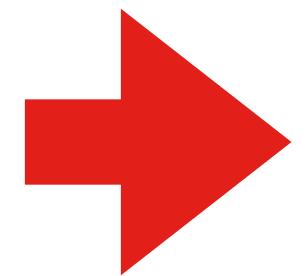

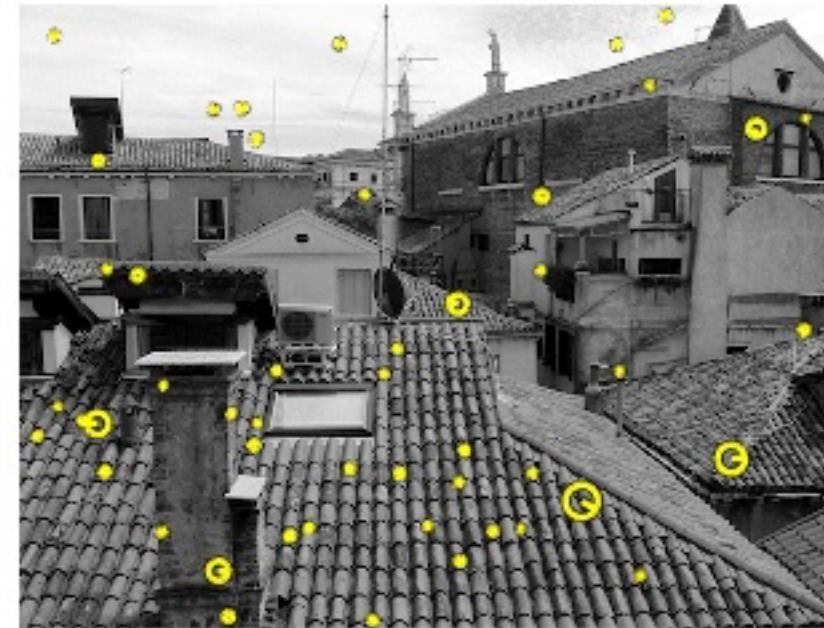

Feature Extraction Techniques

<https://www.vlfeat.org>

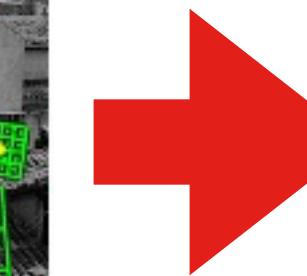

Scale-Invariant Feature Transform (SIFT)

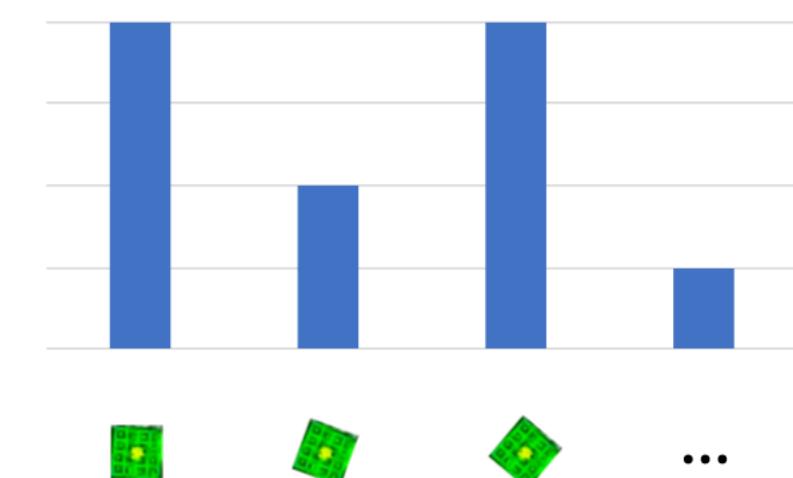

Find “interest points”
in the scene

Compute features at
interest points

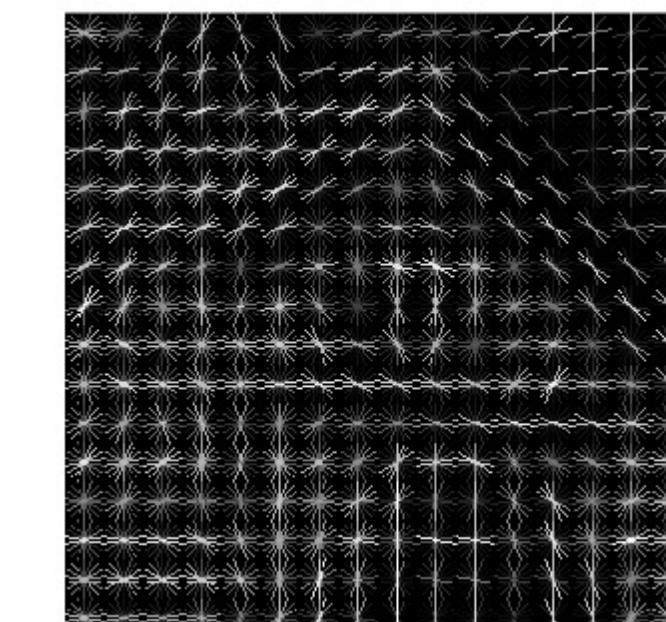

Convert to fixed-dimensional
feature vector
Histogram

Co-variance feature detector

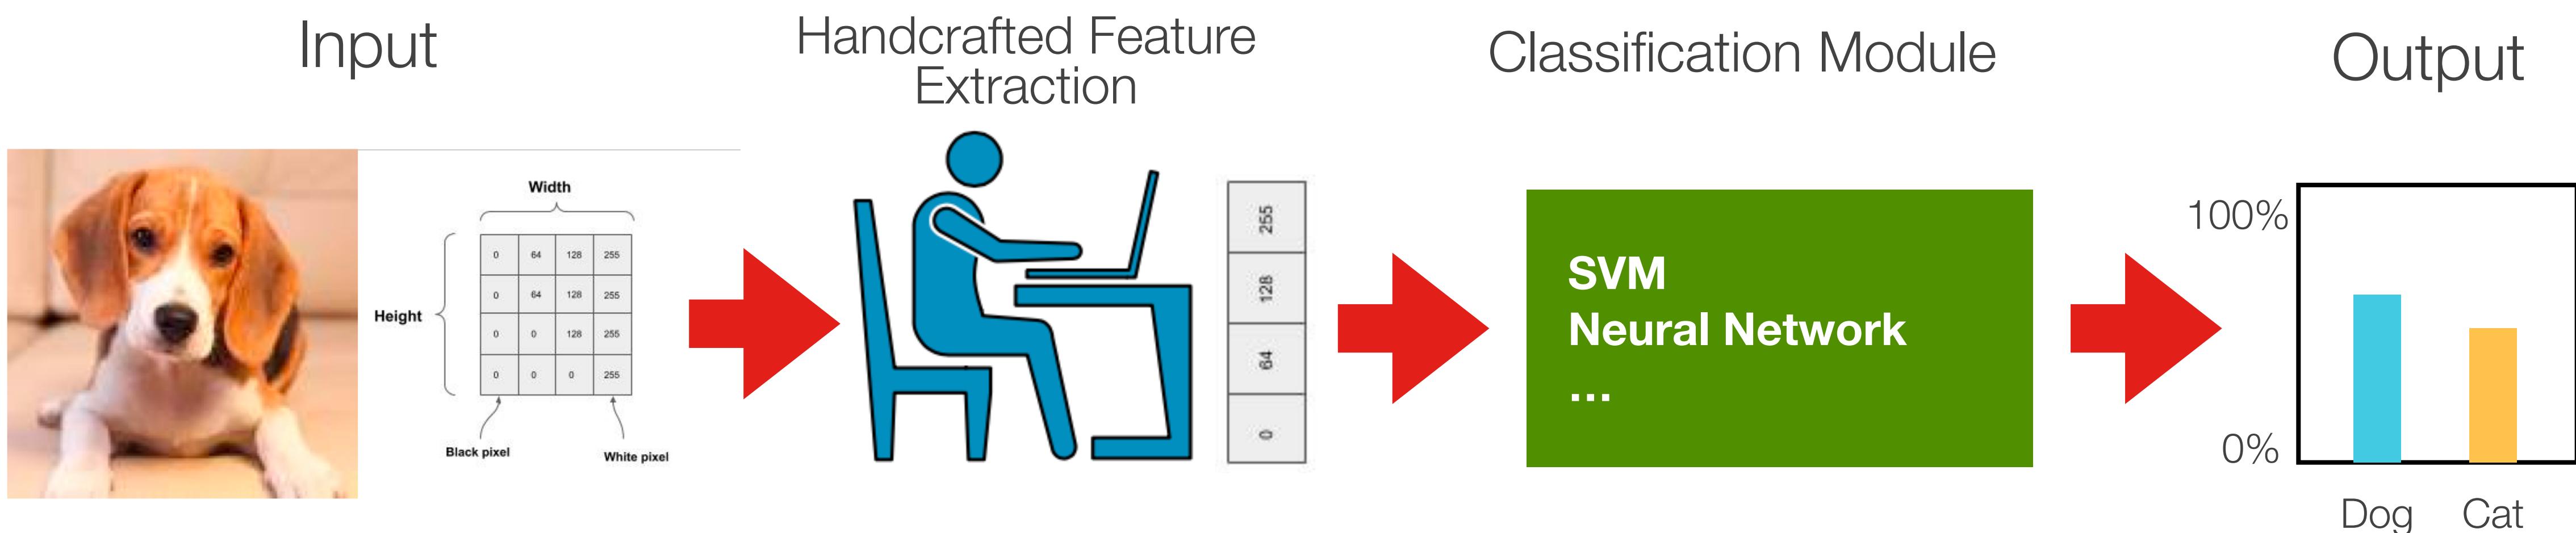

Histogram and oriented gradients

The “old days”: Feature Engineering

- Machine learning models are only as good as the features you provide
- To figure out which features you should use for a specific problem
 - rely on domain knowledge (or partner with domain experts)
 - experiment to create features that make machine learning algorithms work better

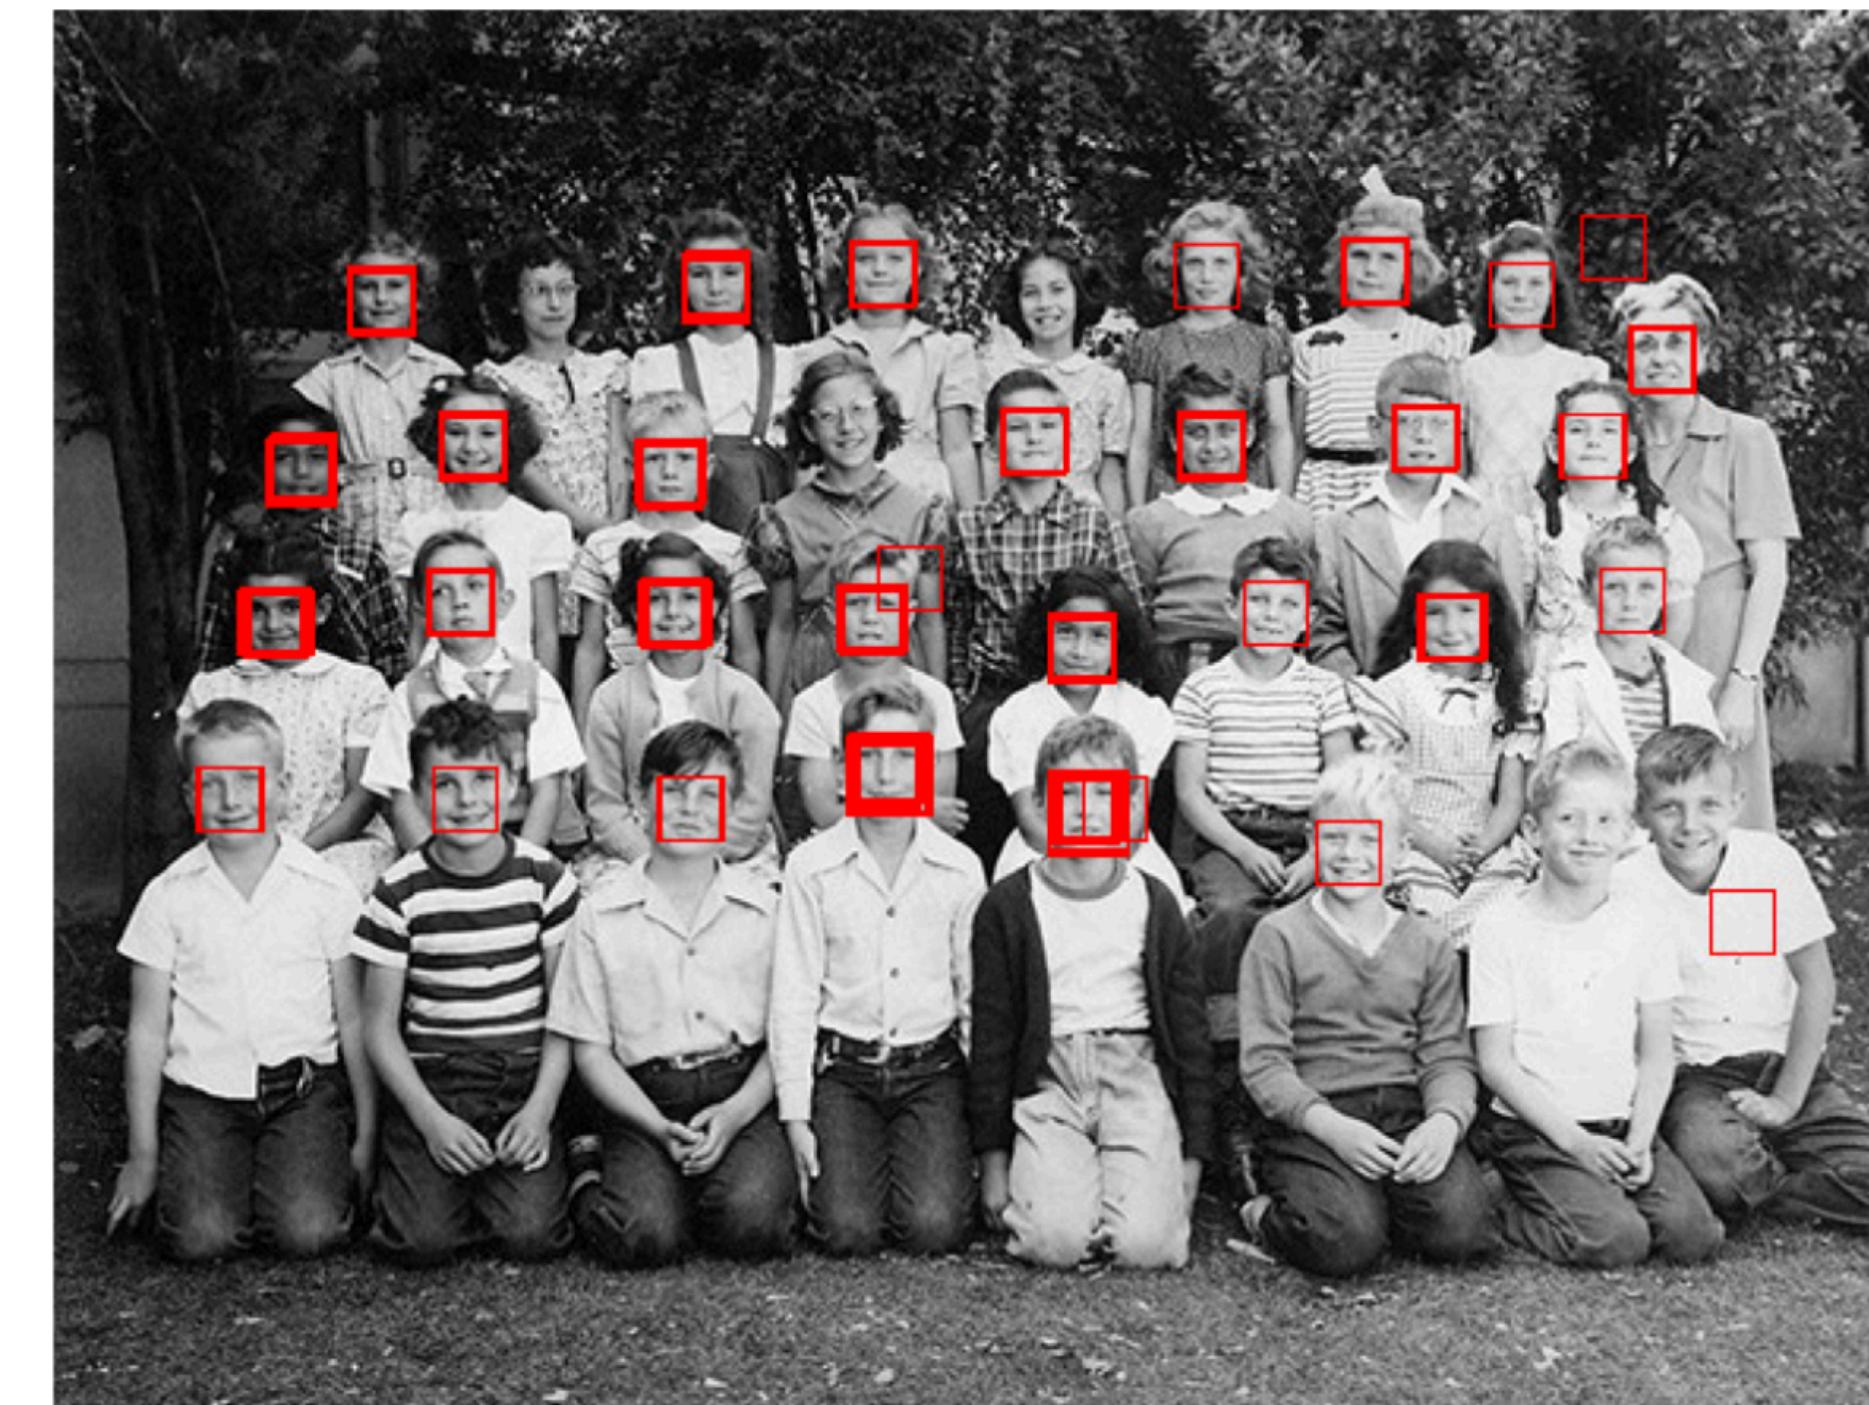

Performance

Object Detection (~2007)

Felzenszwalb, Ramanan, McAllester. A Discriminatively Trained, Multiscale, Deformable Part Model. CVPR 2008 ([DPM v1](#))

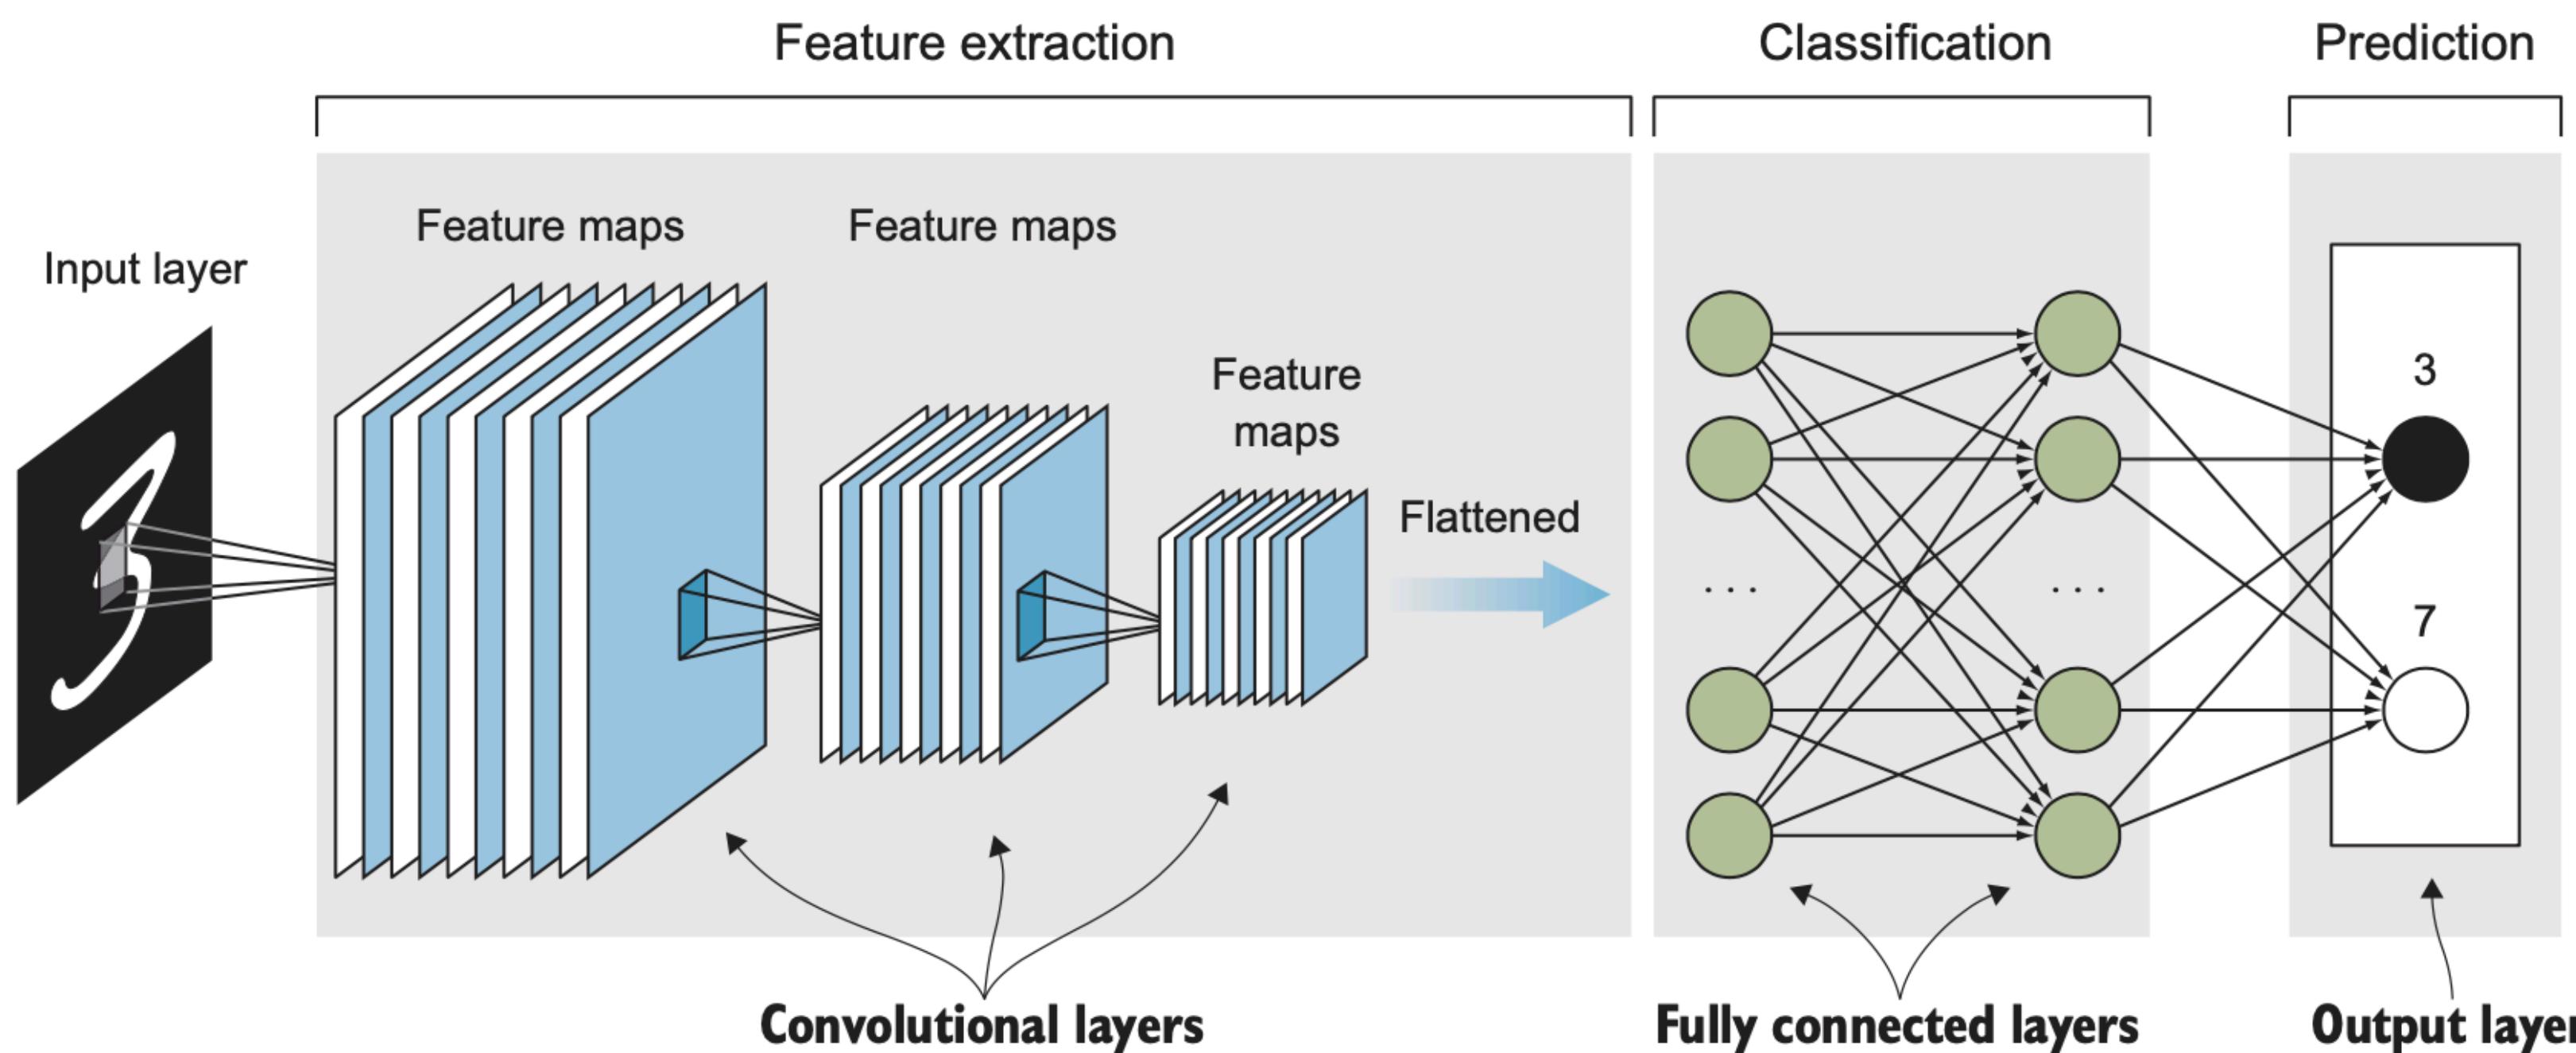

Face Detection (~2013)

Convolutional Neural Networks

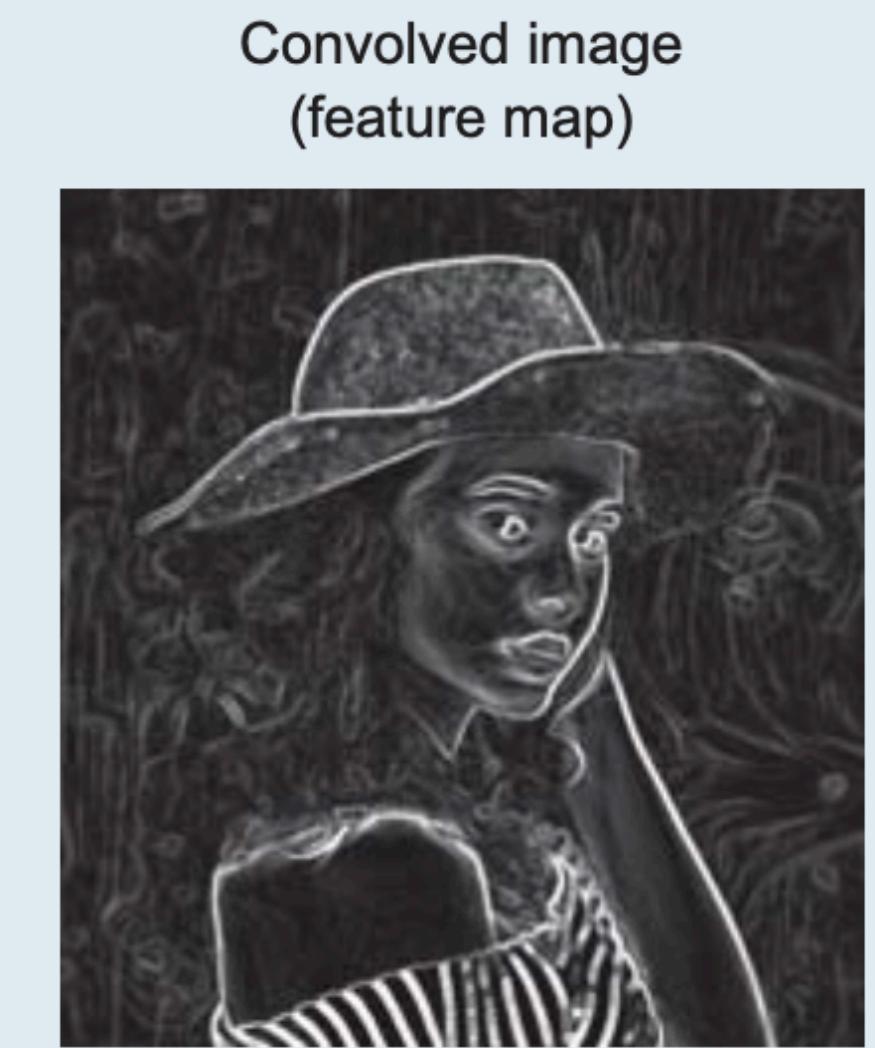

- CNNs exploit image properties to drastically reduce the number of model parameters
- Feature maps
 - **Automatically** extracted hierarchical
 - Retain spatial association between pixels
- **Translation invariance**
 - a dog is a dog even if its image is shifted by a few pixels
- Local interactions
 - all processing happens within very small image windows
 - within each layer, far-away pixels cannot influence nearby pixels

Convolution & Feature Maps

Convolution kernel with optimized weights

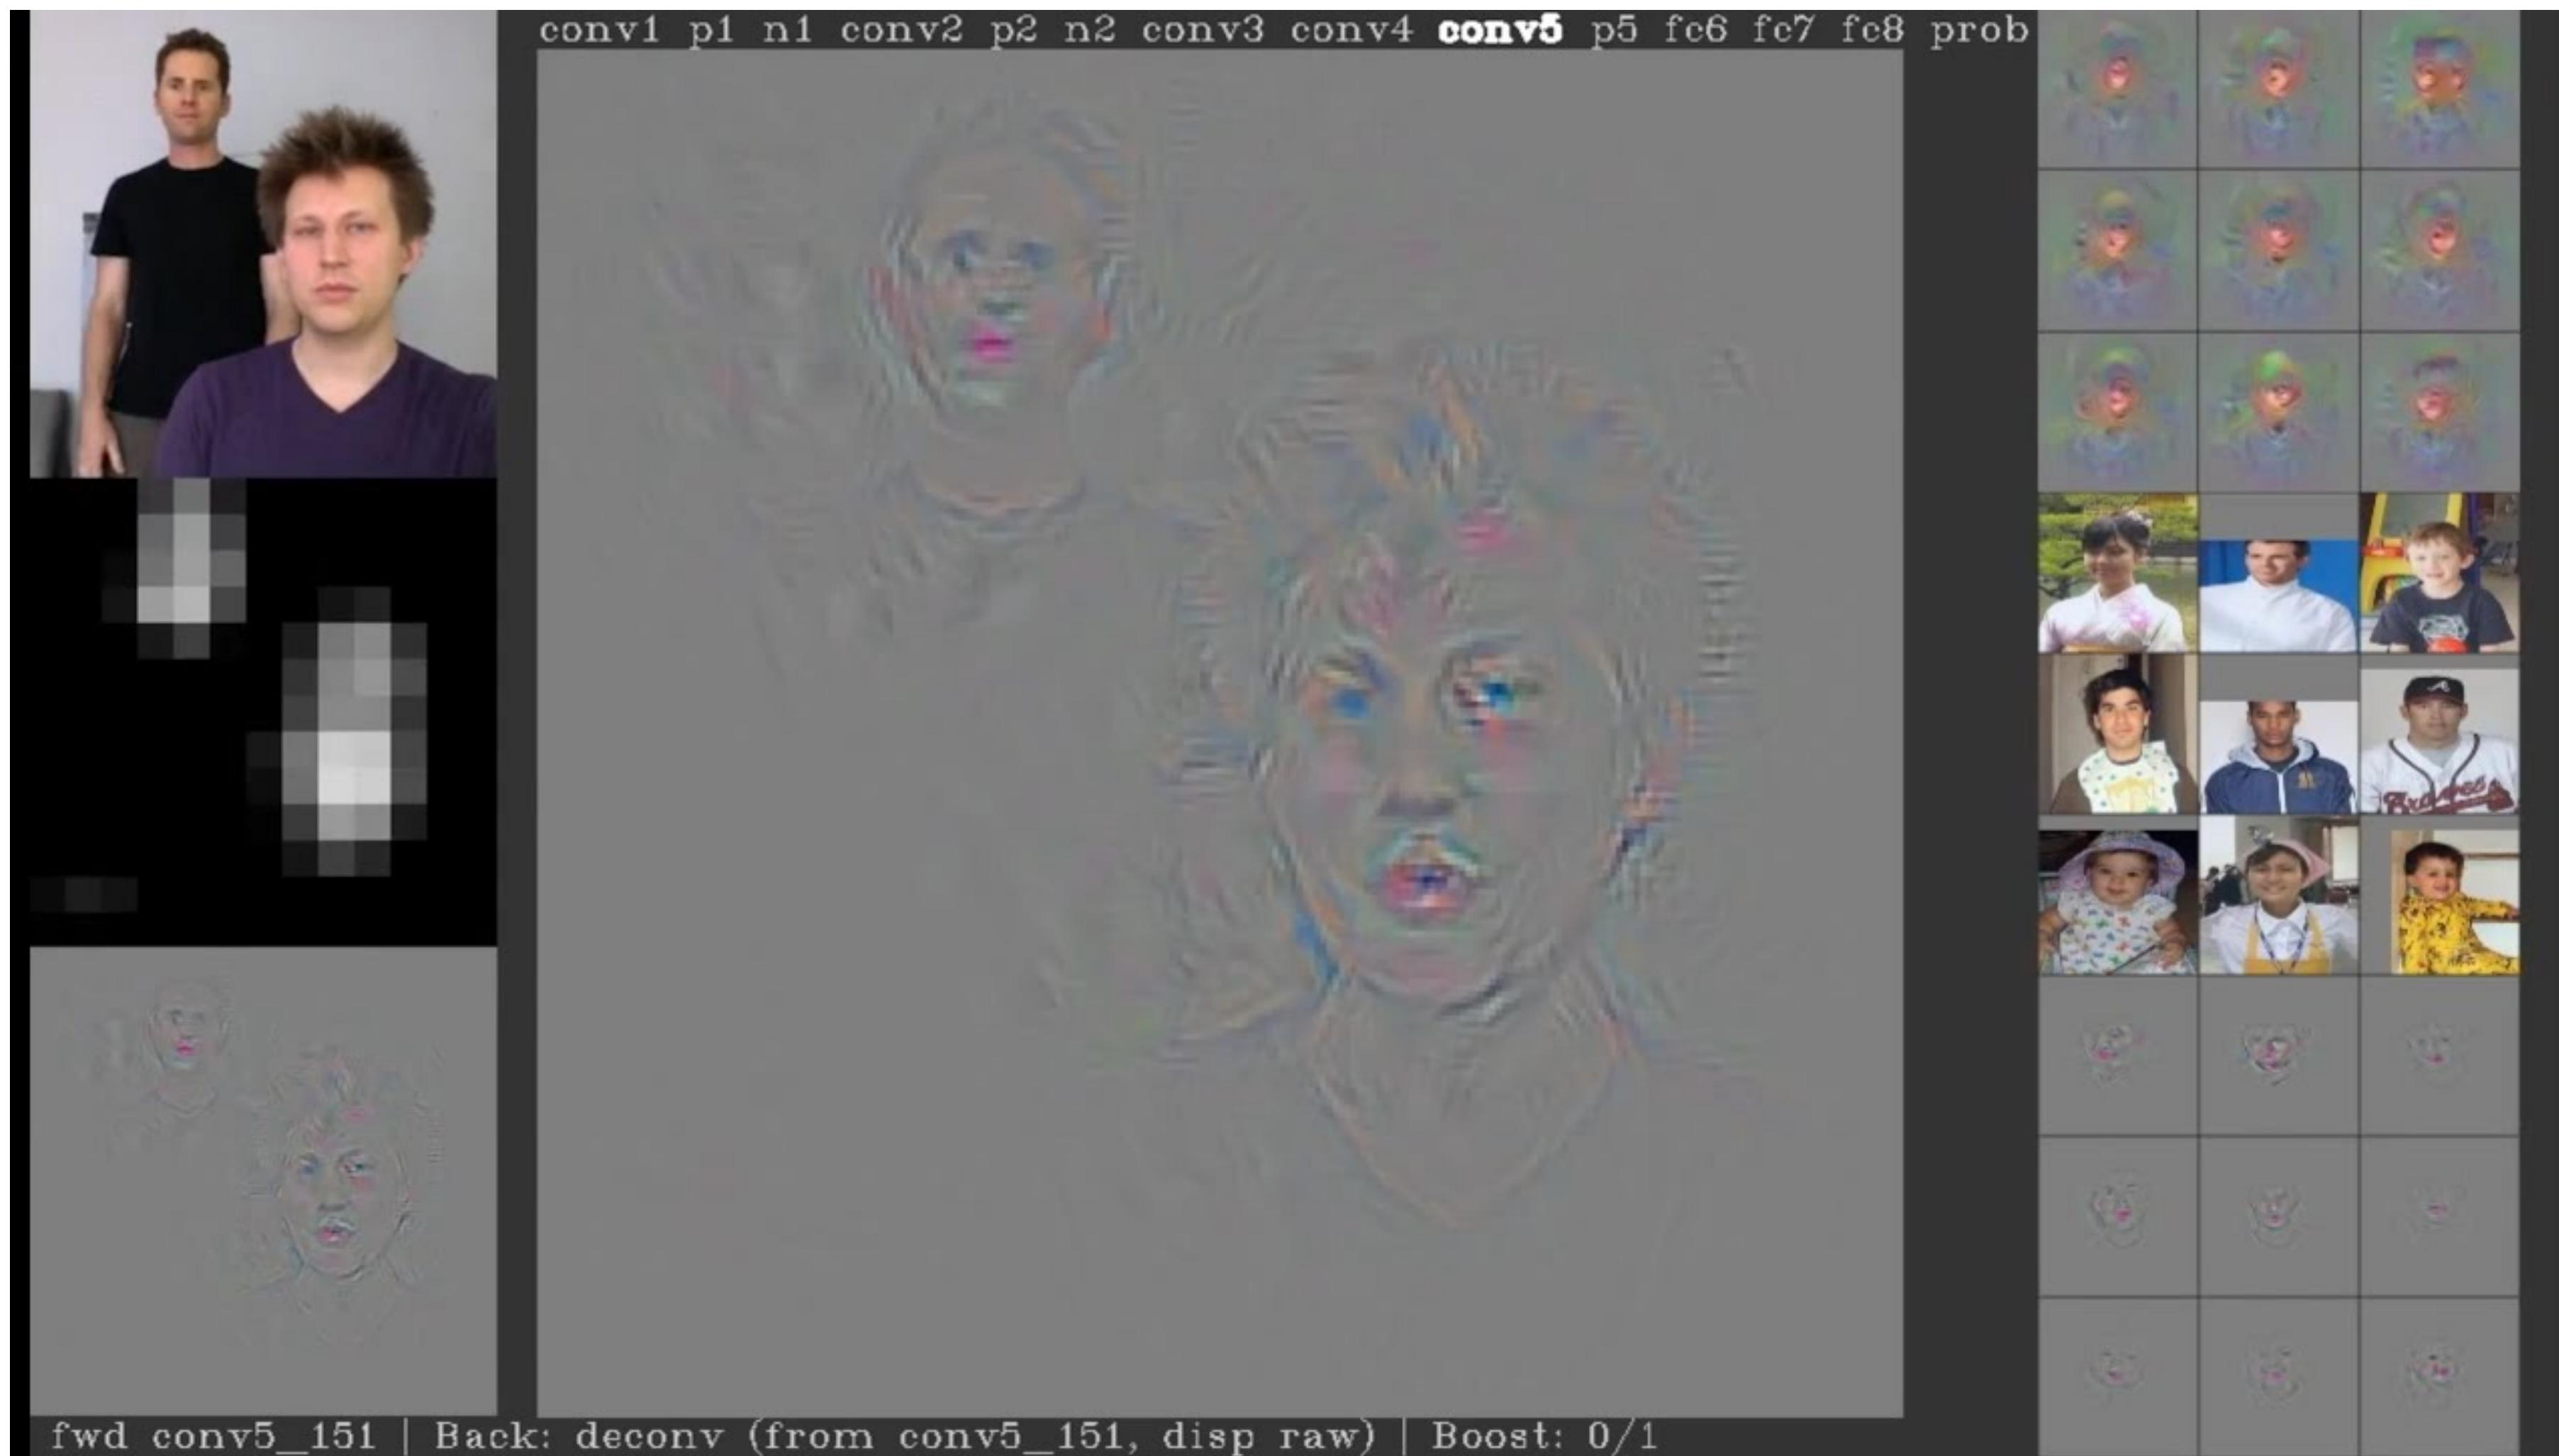

$$\begin{matrix} 0 & -1 & 0 \\ -1 & 4 & -1 \\ 0 & -1 & 0 \end{matrix} * \begin{matrix} 3 & 0 & 1 & 5 & 0 & 3 & 0 & 0 & 3 \\ 2 & 6 & 2 & 4 & 0 & 6 & 1 & 4 & 1 \\ 2 & 4 & 1 & 5 & 0 & 3 & 0 & 2 & 0 \\ 2 & 0 & 1 & 5 & 0 & 3 & 2 & 3 & 1 \\ 3 & 0 & 2 & 4 & 3 & 2 & 1 & 1 & 1 \\ 2 & 6 & 2 & 4 & 0 & 6 & 3 & 6 & 1 \\ 2 & 4 & 1 & 0 & 6 & 0 & 3 & 6 & 1 \\ 2 & 6 & 2 & 4 & 4 & 0 & 3 & 6 & 1 \\ 2 & 4 & 1 & 0 & 6 & 1 & 6 & 1 & 1 \end{matrix} = \begin{matrix} -3 \end{matrix}$$

Network dissection

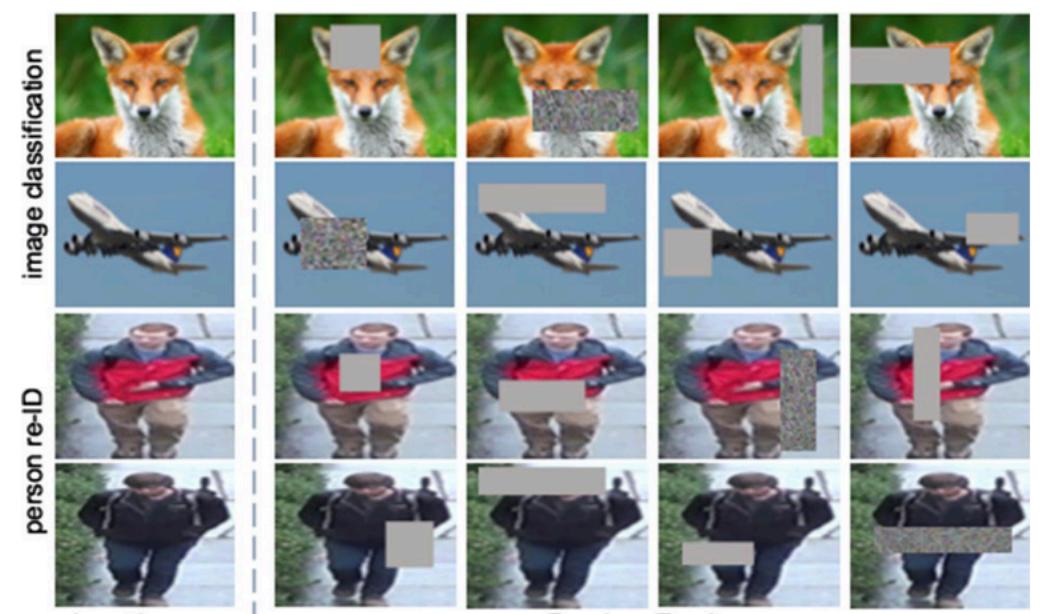

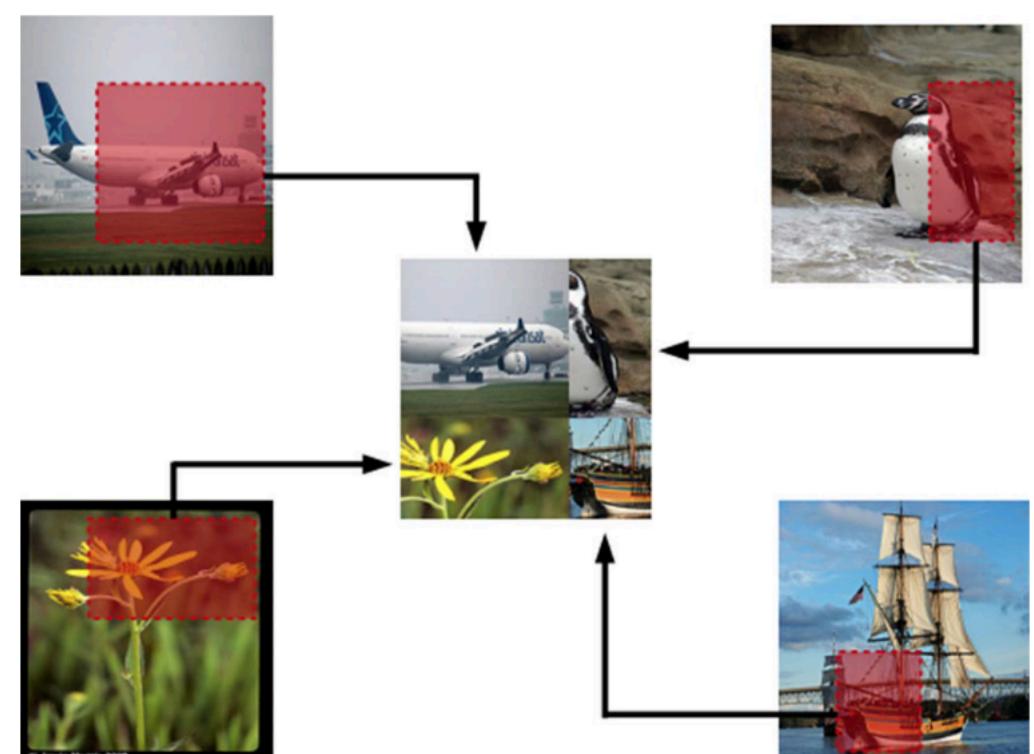

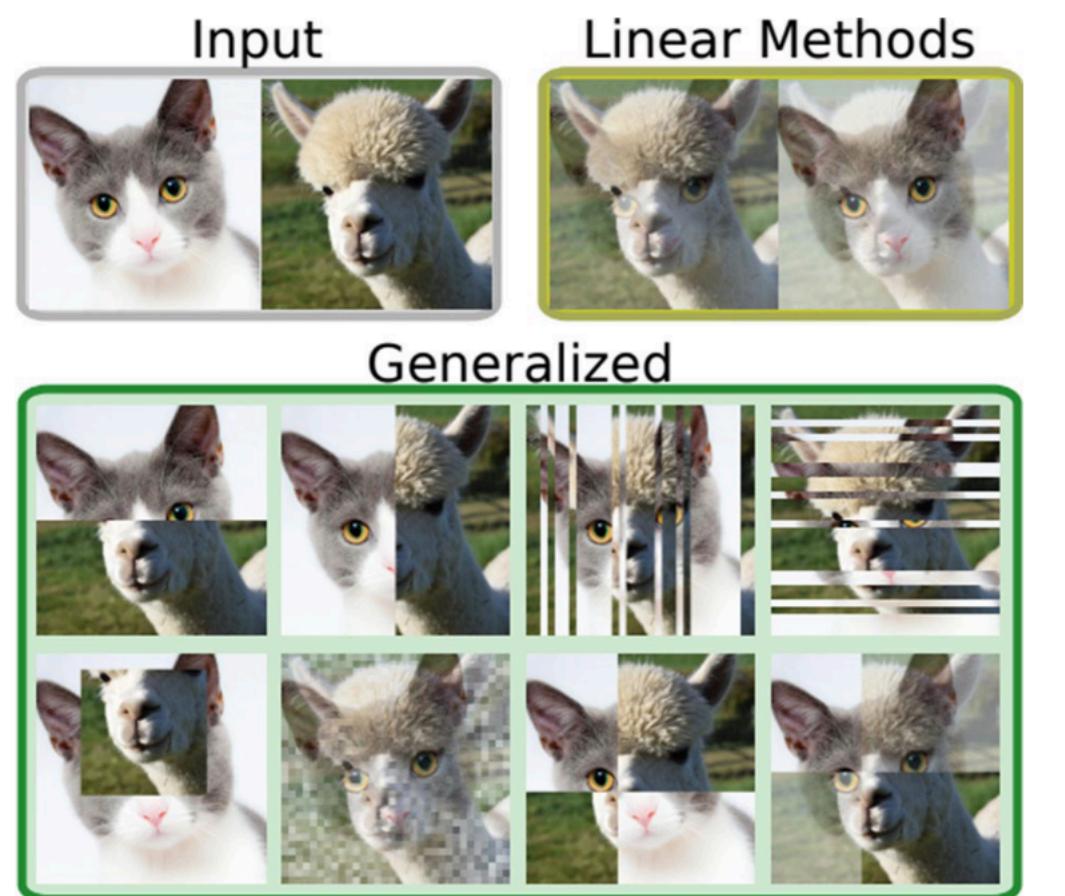

Translation Invariance

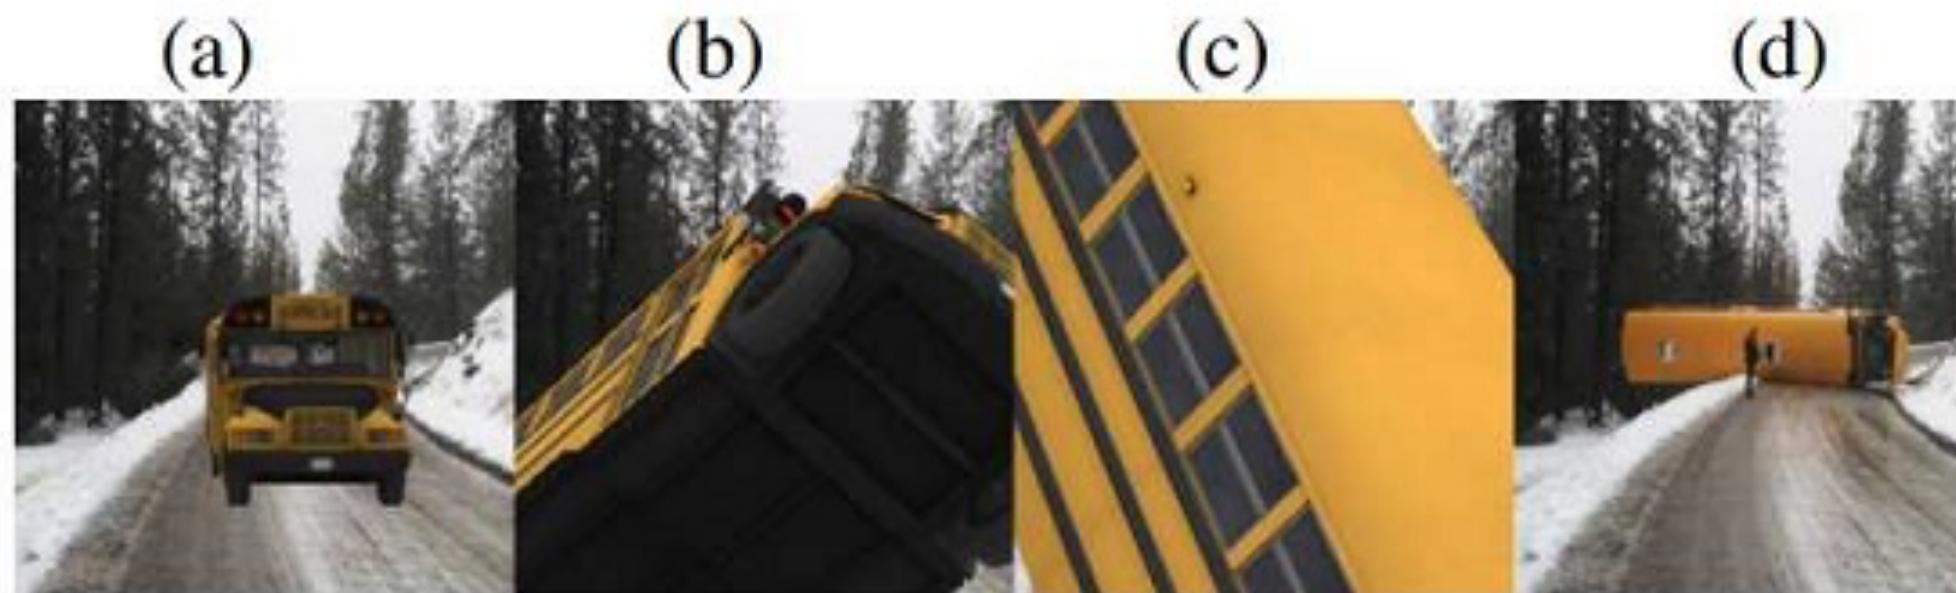

- But not rotation and scaling invariance!

Data Augmentation

- Generate variations of the input data, to improve generalisability (out of distribution inputs)
 - Improve invariance (rotation, scaling, distortion)
- Geometric
 - Flipping
 - Color space
 - Cropping
 - Rotation
 - Translation
 - Noise Injection
- Color space transformation
- Mixing Images
- Random erasing
- Adversarial training
- GAN-based image generation

Robustness to input variation

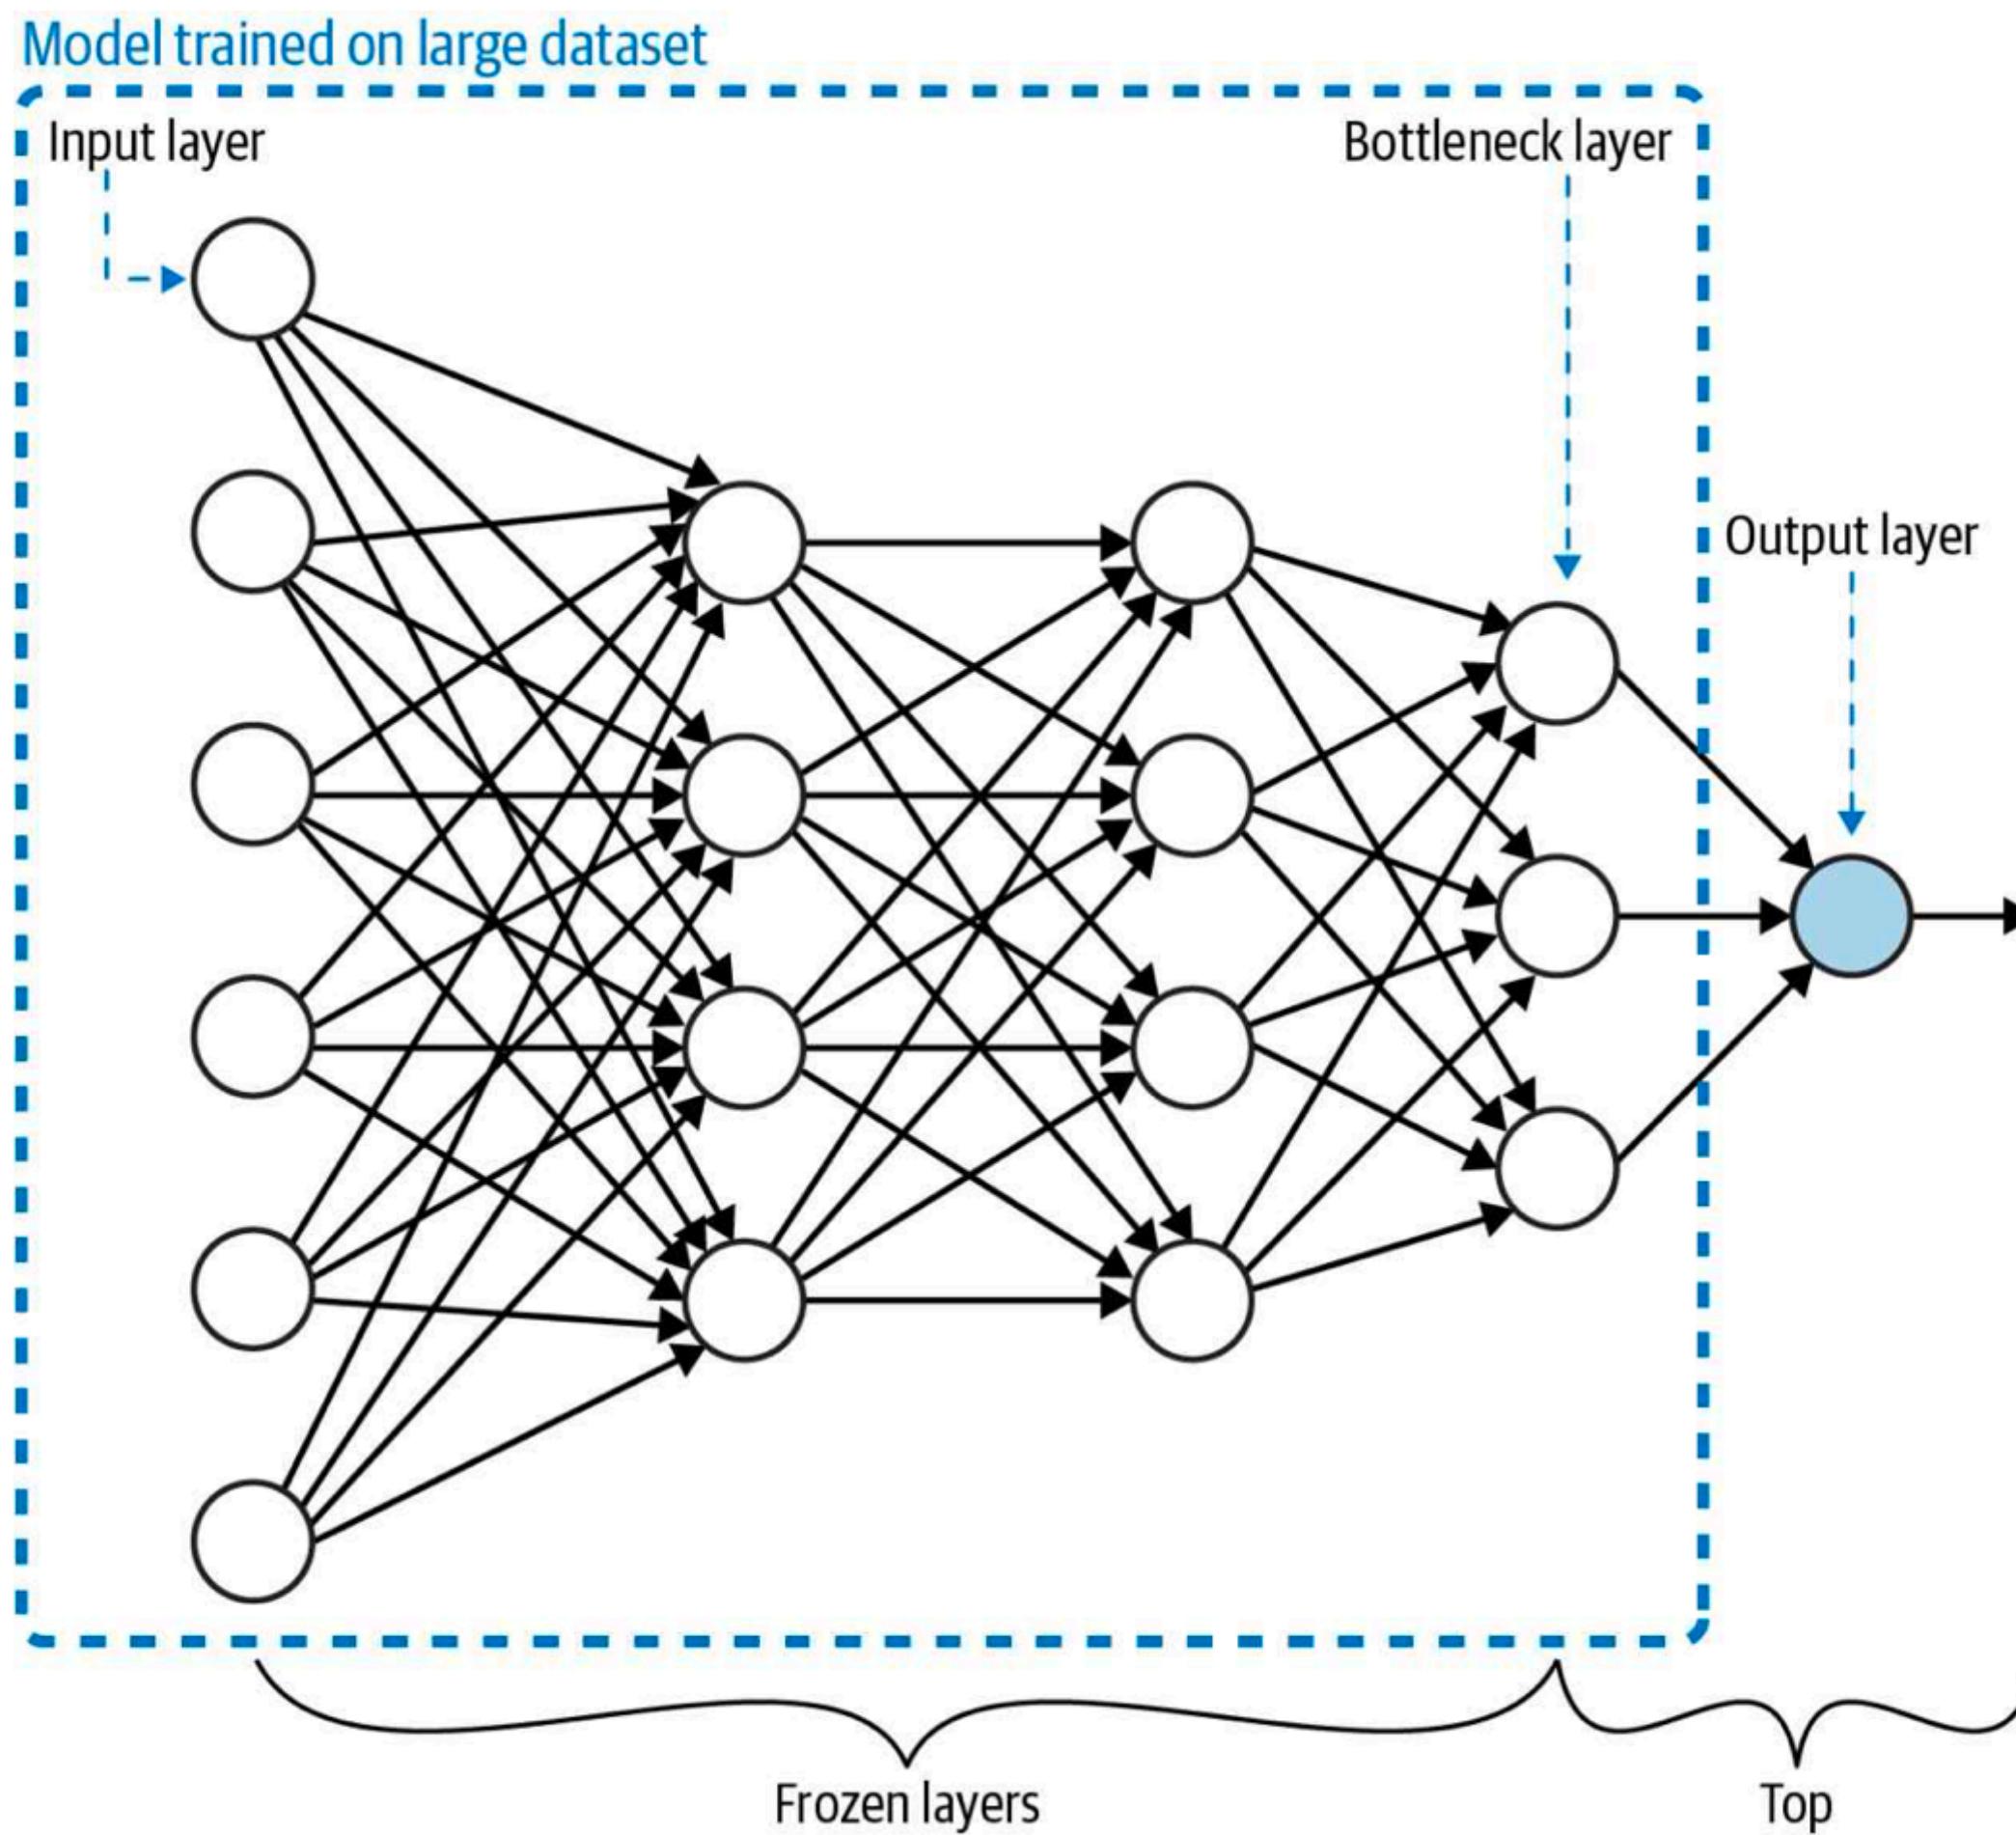

Strike (with) a Pose: Neural Networks Are Easily Fooled by Strange Poses of Familiar Objects.
Alcorn et al. 2019

<https://arxiv.org/pdf/1811.11553.pdf>

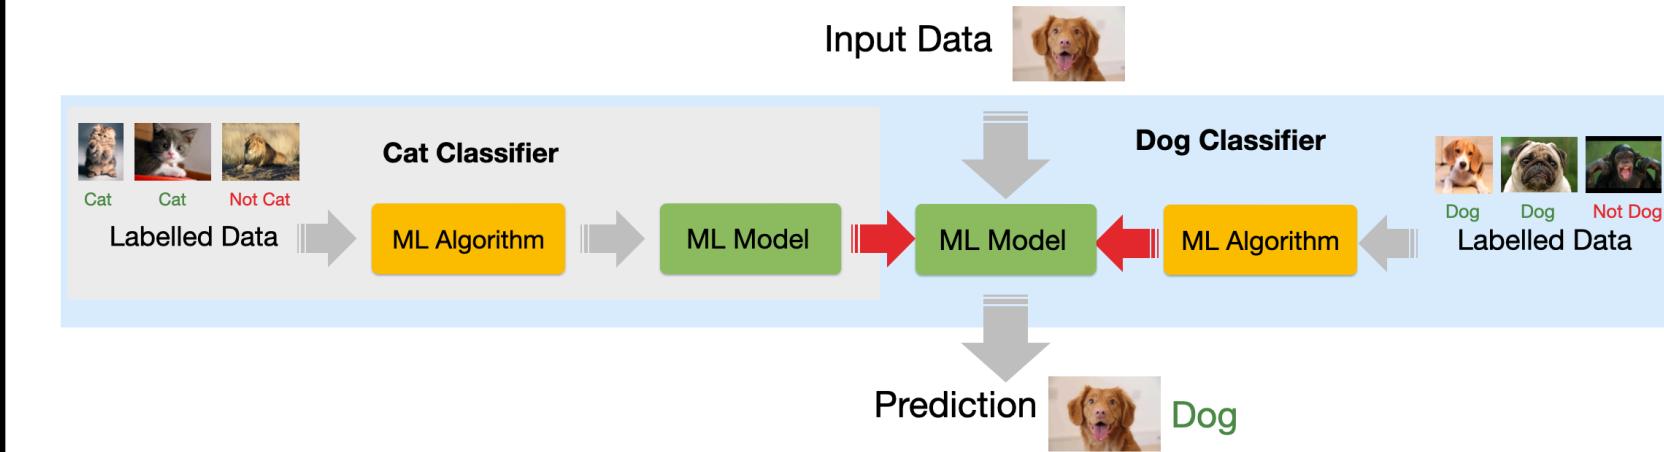

Transfer Learning

Transfer Learning

Reuse a model trained for one task is re-purposed (tuned) on a different but related task

Useful in tasks lacking abundant data

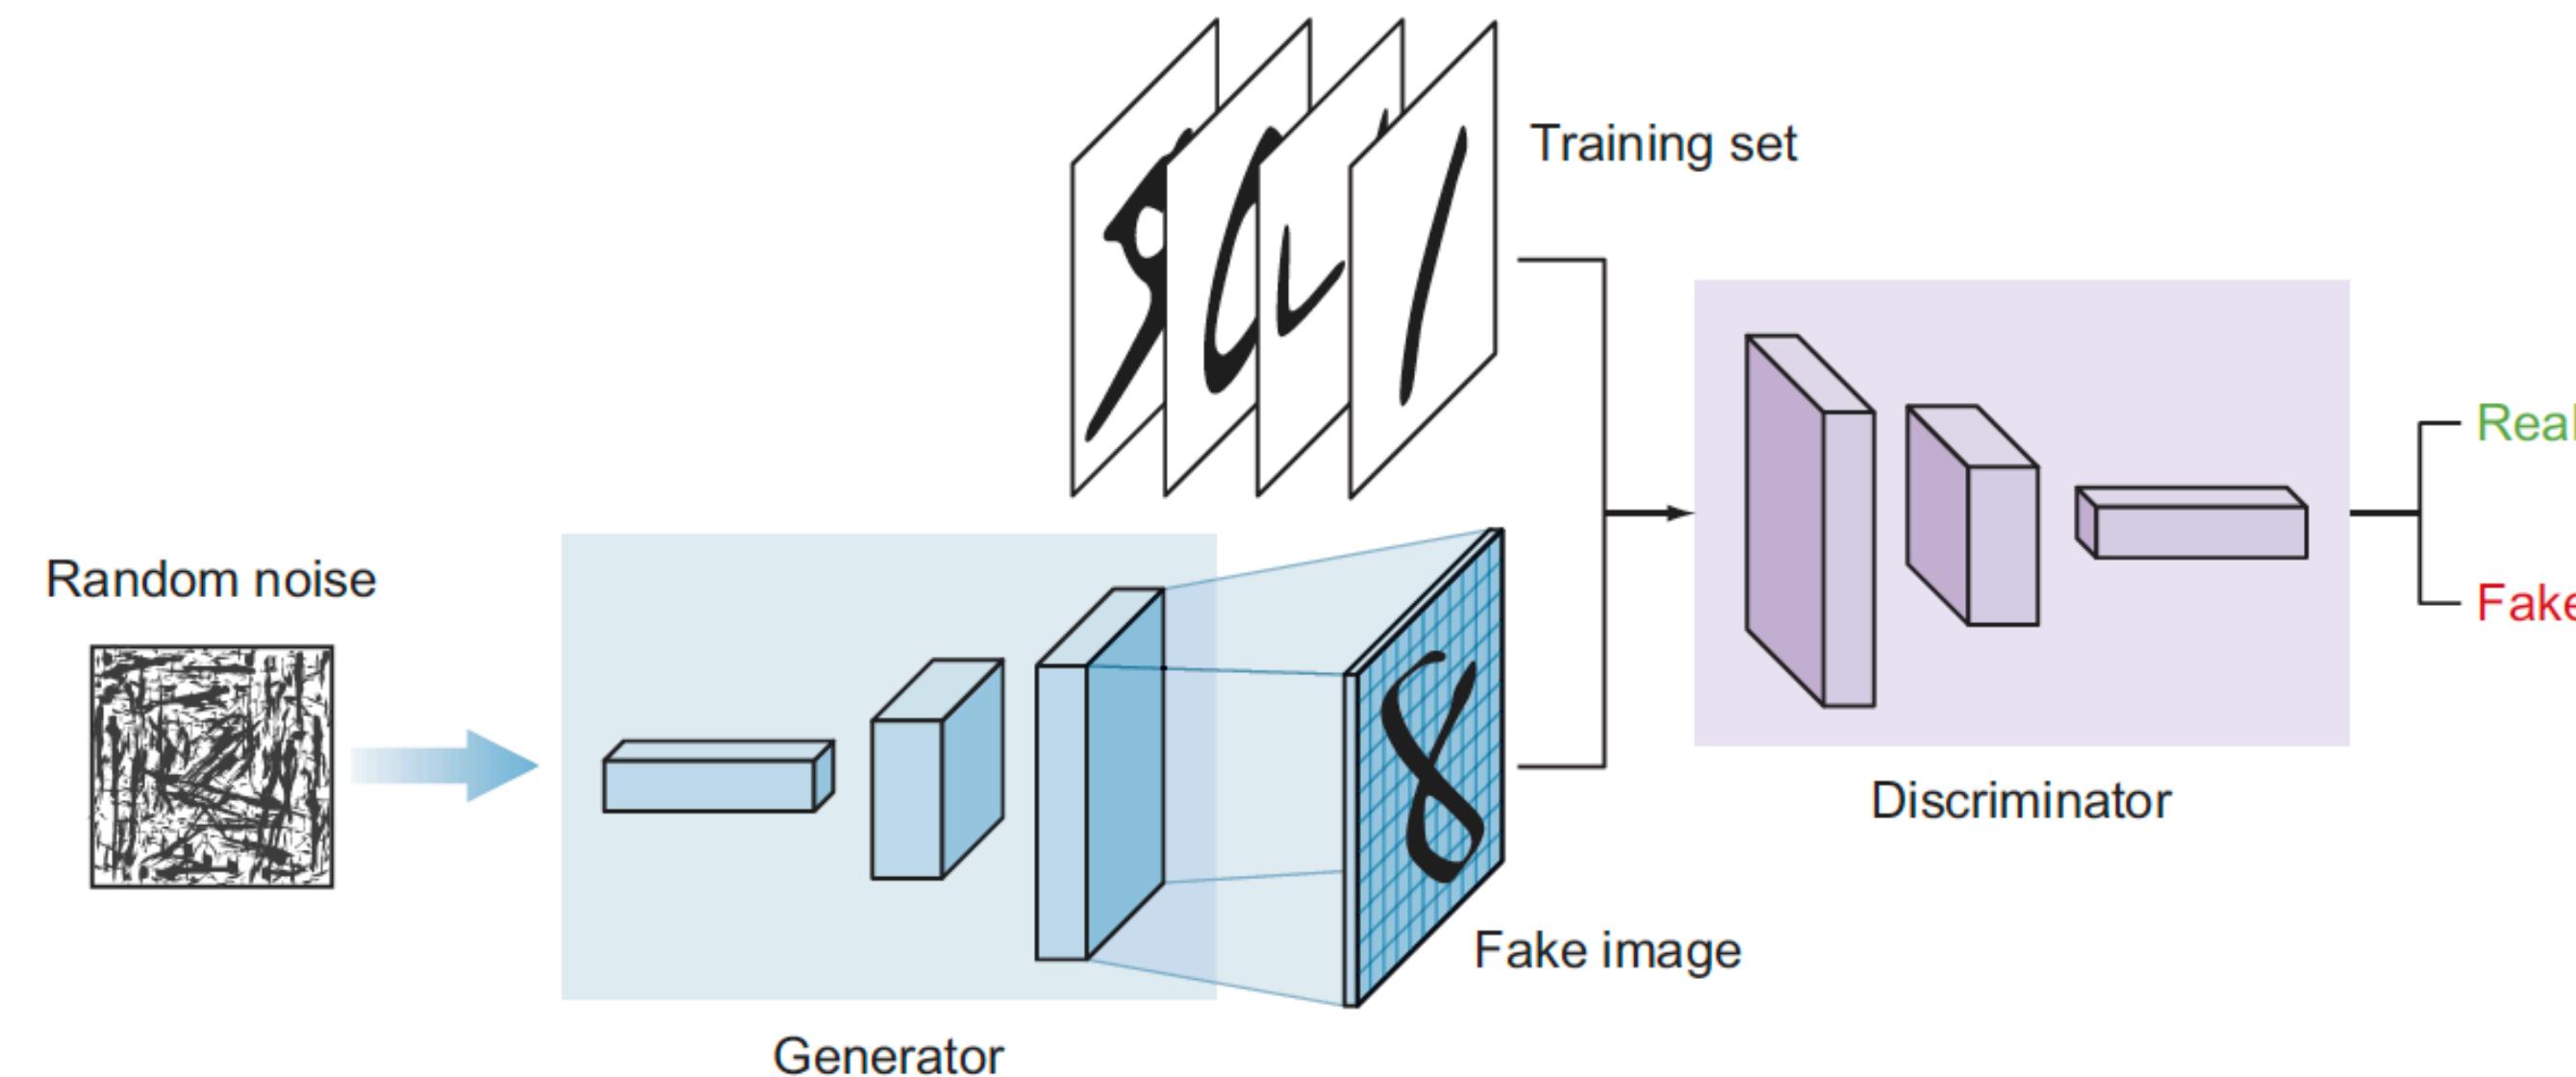

- **Problem:** training custom ML models requires extremely large datasets
- **Transfer learning:** take a model that has been trained on the **same type of data for a similar task** and apply it to a specialised task using our own custom data.
 - **Same data:** same data modality, same types of images (e.g. professional pictures vs. Social media pictures)
 - **Similar tasks:** if you need a new object classification model, use a model pre-trained for object classification

Advanced Computer Vision Techniques

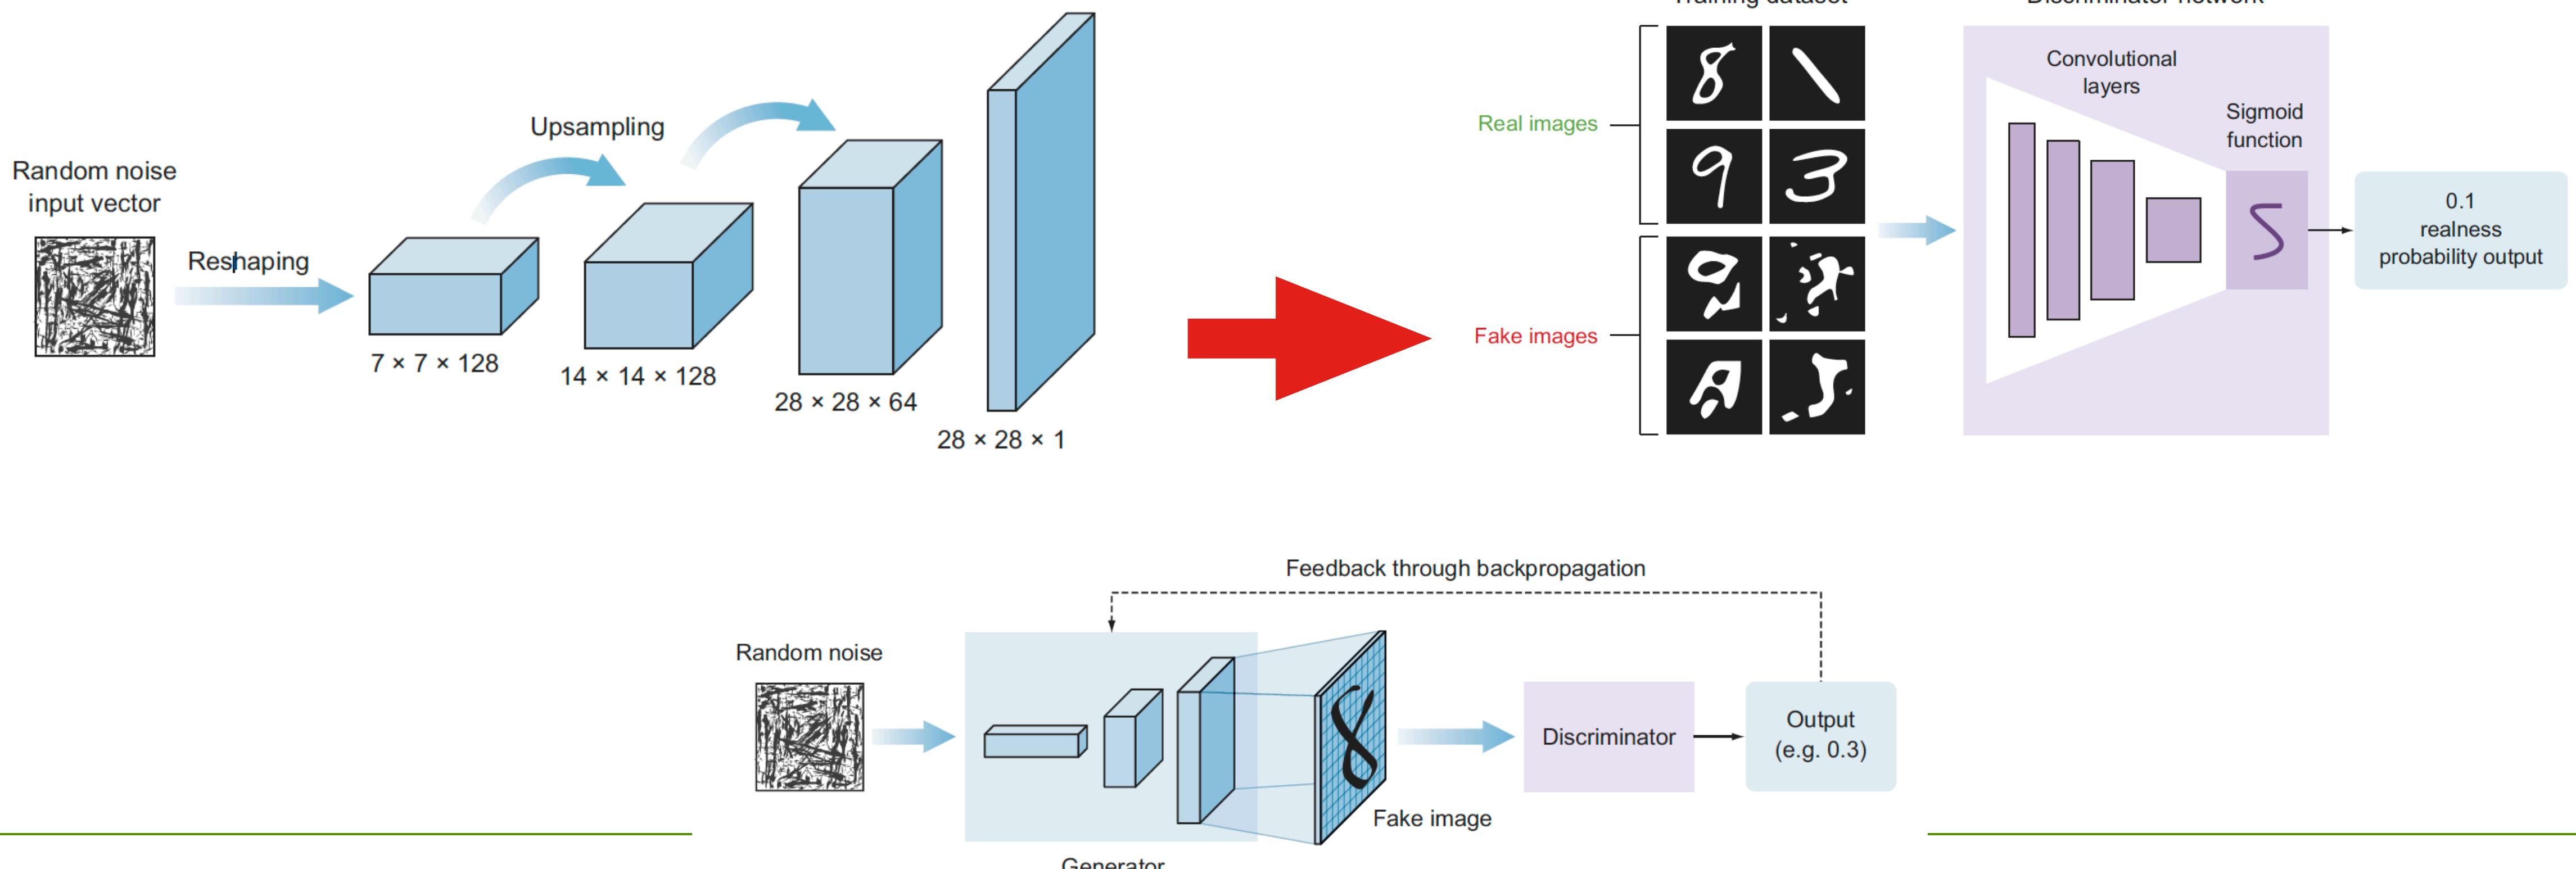

Generative Adversarial Networks

- Learn patterns from the training dataset and create new images that have a similar distribution of the training set
- Two deep neural networks that compete with each other
 - The generator tries to convert random noise into observations that look as if they have been sampled from the original dataset
 - The discriminator tries to predict whether an observation comes from the original dataset or is one of the generator's forgeries

Generative Adversarial Networks

- The generator's architecture looks like an inverted CNN that starts with a narrow input and is upsampled a few times until it reaches the desired size
- The discriminator's model is a typical classification neural network that aims to classify images generated by the generator as real or fake

Image super-resolution GAN

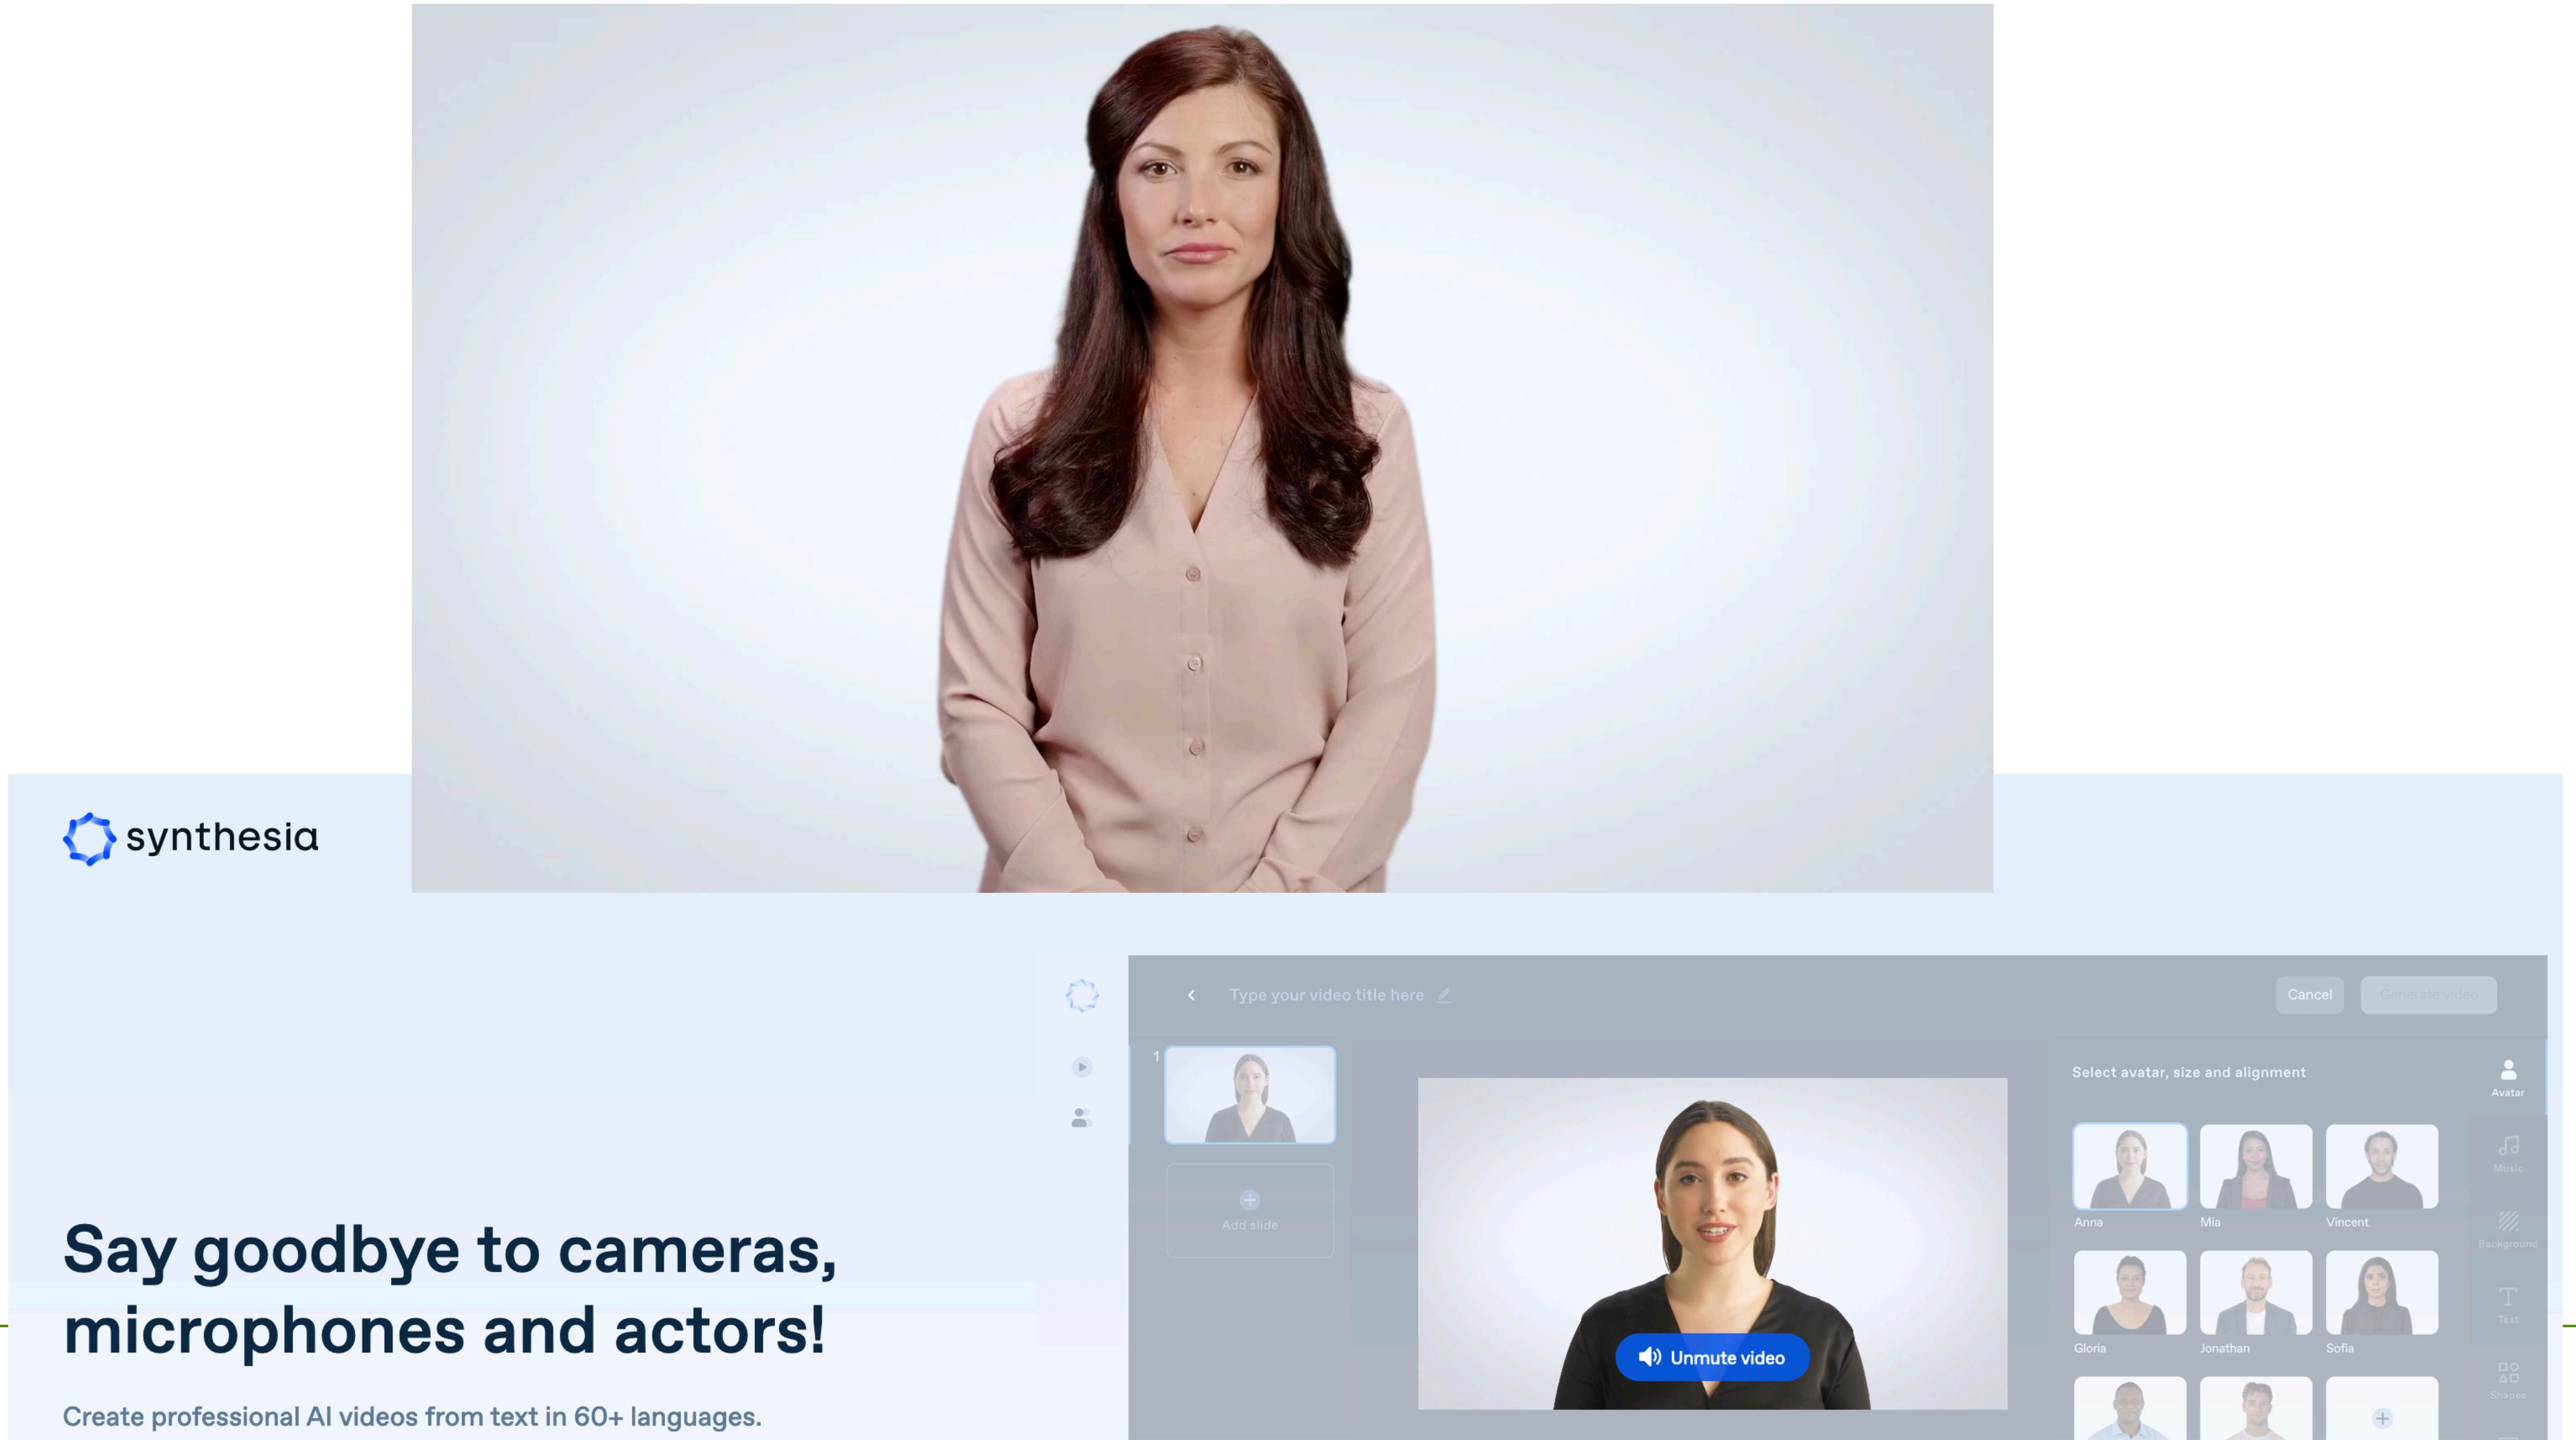

- A good technical summary

[https://blog.paperspace.com/
image-super-resolution/](https://blog.paperspace.com/image-super-resolution/)

<https://newatlas.com/super-resolution-weizmann-institute/23486/>

Synthetic Video Generation

The image shows a screenshot of the Synthesia video generation software. At the top, there is a large thumbnail of a woman with long dark hair, wearing a light pink button-down shirt. In the bottom left corner of the thumbnail, the Synthesia logo (a blue hexagon icon) and the word "synthesia" are visible. Below the thumbnail, a large text block reads: "Say goodbye to cameras, microphones and actors!". Underneath this text, a smaller line of text says: "Create professional AI videos from text in 60+ languages.". To the right of the main image, there is a video player window showing the same woman's face. The video player has standard controls: a play button, a volume icon with the text "Unmute video", and a "Generate video" button at the top right. On the far right of the interface, there is a sidebar titled "Select avatar, size and alignment" which lists several pre-made avatars: Anna, Mia, Vincent, Gloria, Jonathan, and Sofia. There are also tabs for "Avatar", "Music", "Background", "Text", and "Shapes".

Text-to-image Generation
